4. Changes to the Firebird API and ODS

ODS (On-Disk Structure) Changes

New ODS Number

New System Tables

New Columns in System Tables

Application Programming Interfaces

Services Cleanup

Services API Extensions

Timeouts for Sessions & Statements

New Isolation Sub-level for READ COMMITTED Transactions

Support for Batch Insert and Update Operations in the API

API Support for Time Zones

API Support for DEC_FLOAT and Long Numerics

Additions to Other Interfaces

Extensions to various getInfo() Methods

Additions to the Legacy (ISC) API

5. Reserved Words and Changes

New Keywords in Firebird 4.0

Reserved

Non-reserved

6. Configuration Additions and Changes

Parameters for Timeouts

ConnectionIdleTimeout

StatementTimeout

Parameters for External Connection Pooling

ExtConnPoolSize

ExtConnPoolLifetime

Parameters to Restrict Length of Object Identifiers

MaxIdentifierByteLength

MaxIdentifierCharLength

Parameters Supporting Read Consistency in Transactions

ReadConsistency
8. Management Statements

Connections Pooling Management

ALTER EXTERNAL CONNECTIONS POOL

ALTER SESSION RESET

Chapter 1. General Notes

Thank you for choosing Firebird 4.0. We cordially invite you to test it hard against your expectations and engage with us in identifying and fixing any bugs you might encounter.

ODS 13 is introduced and it's a major ODS upgrade, so older databases cannot be opened with a Firebird 4 server. The engine library is named `engine13.dll` (Windows) and `libEngine13.so` (POSIX). The security database is named `security4.fdb`. Binaries layout and configuration are unchanged from Firebird 3.

That said, you can copy the Firebird engine library from the Firebird 3.0 distribution package (named `engine12.dll` (Windows) and `libEngine12.so` (POSIX), and located inside the `/plugins` sub-directory) to continue working with databases in ODS12 without needing a backup/restore. However, new features introduced with Firebird 4.0 will not be accessible.

Known incompatibilities are detailed in the Compatibility Issues chapter.

Bug Reporting

Bugs fixed since Firebird 3.0.7 and Firebird 4.0 Release Candidate 1 are listed and described in the Bugs Fixed chapter.

• If you think you have discovered a new bug in this release, please make a point of reading the instructions for bug reporting in the article How to Report Bugs Effectively, at the Firebird Project website.

• If you think a bug fix has not worked, or has caused a regression, please locate the original bug report in the Tracker, reopen it if necessary, and follow the instructions below.

Follow these guidelines as you attempt to analyse your bug:

1. Write detailed bug reports, supplying the exact build number of your Firebird kit. Also provide details of the OS platform. Include reproducible test data in your report and post it to our Tracker.

2. You are warmly encouraged to make yourself known as a field-tester of this beta by subscribing to the field-testers' list and posting the best possible bug description you can.

3. If you want to start a discussion thread about a bug or an implementation, please do so by subscribing to the firebird-devel list.

Documentation

You will find all of the README documents referred to in these notes — as well as many others not referred to — in the doc sub-directory of your Firebird 4.0 installation.

— The Firebird Project
Chapter 2. New In Firebird 4.0

Summary of New Features

The following list summarises the features and changes, with links to the chapters and topics where more detailed information can be found.

Complete In Firebird 4.0 Final Release

Renamed functions RSA_SIGN and RSAVERIFY

Functions priorly introduced as RSA_SIGN and RSA_VERIFY have been renamed to RSA_SIGN_HASH and RSA_VERIFY_HASH respectively.

Tracker ticket #6806

Session time zone is available via the system context

The SYSTEM namespace of the built-in function RDB$GET_CONTEXT has been extended with the SESSION_TIMEZONE parameter that returns the time zone of the current session.

Tracker ticket #6786

More efficient implementation of SUBSTRING for UTF-8 character set

Built-in function SUBSTRING has been improved to provide better performance when called with UTF-8 input strings.

Tracker ticket #6769

Allow replication plugins to refuse the current attachment

The replication plugin API has been extended to allow the plugin to validate the attachment and return an error if it refuses to replicate its changes.

Tracker ticket #6767

Immediate execution of DSQL_drop and DSQL_unprepare commands

Delayed execution of DSQL_drop and DSQL_unprepare options of the dsq1_free_statement() operation has been replaced with an immediate execution in order to release resource locks faster.

Tracker ticket #6748

Provide time zone ID constants in public headers

Time zone IDs used by the Firebird engine have been made available in the header files of the public API.

Tracker ticket #6715

Make RDB$GET_TRANSACTION_CN working the same way in Super and Classic

Built-in function GET_TRANSACTION_CN has been fixed to return the same result (proper commit
number) for the given transaction number in all architectures. Priorly it might return NULL in Classic Server.

Tracker ticket #6253

**Complete In Release Candidate 1**

**ALTER SESSION RESET statement**

New command to reset user session environment to its initial (default) state has been added.

For full details, see ALTER SESSION RESET Statement in the Management Statements chapter.

Tracker ticket CORE-5832

**New virtual table RDB$CONFIG**

This table exposes configuration settings actual for the current database.

For full details, see Virtual table RDB$CONFIG in the Engine chapter.

Tracker ticket CORE-3708

**Report replica mode through isc_database_info, MON$DATABASE and SYSTEM context**

The replica state of the database (none / read-only / read-write) is now surfaced via the MON$DATABASE table and Attachment::getInfo() API call. It can also be read using the context variable REPLICA_MODE of the SYSTEM namespace.

For full details, see Monitoring in the Monitoring & Command-line Utilities chapter and Extensions to various getInfo() Methods in the Changes to the Firebird API and ODS chapter.

Tracker ticket CORE-6474

**Tracing of session management statements**

The trace manager has been extended to report also the new category of session management statements, e.g. ALTER SESSION RESET.

Trace plugin developers should be prepared to accept the NULL transaction inside the ITracePlugin::trace_dsql_execute() method, similarly to how it should have been handled for the trace_dsql_prepare() method of the same interface.

Tracker ticket CORE-6469

**Ability to retrieve next attachment ID and next statement ID**

Counters representing next attachment ID and next statement ID are now surfaced via the MON$DATABASE table and Attachment::getInfo() API call.

For full details, see Monitoring in the Monitoring & Command-line Utilities chapter and Extensions to various getInfo() Methods in the Changes to the Firebird API and ODS chapter.

Tracker ticket CORE-6300
**SQL standard syntax for timezone offsets**
Timezone offset in timestamp/time literal, CAST, SET TIME ZONE and AT TIME ZONE now follows SQL standard syntax only.

Tracker ticket CORE-6429

**No -pidfile option anymore**
PIDFile/-pidfile directive/option has been removed from Firebird Super(Server/Classic) systemd unit.

Tracker ticket CORE-6413

**Time zone displacement in configuration**
Usage of time zone displacement is now allowed in configuration setting DefaultTimeZone.

Tracker ticket CORE-6395

**Better dependency tracking when installing Firebird on Linux**
Presence of tomcrypt & curses libraries is now checked before installing Firebird.

Tracker ticket CORE-6366

**INT128 as a dedicated data type**
INT128 data type has been added as explicit basic type for high precision numerics.

Tracker ticket CORE-6342

**API cleanup**
Util methods that return interface pointers by legacy handle are replaced with plain C functions.

Tracker ticket CORE-6320

**Ability to update the supported time zones**
Now it’s possible to update list of time zones (names and ids) without source code recompilation.

Tracker ticket CORE-6308

**Support for nbackup -fixup via Services API**
Allow to fixup (nbackup) a database using Services API

Tracker ticket CORE-5085

**Better error reporting for user management commands**
Explicit message about missing password is now raised for CREATE [OR ALTER] USER statements.

Tracker ticket CORE-4841

**Improved sorting performance**
Sorting performance has been improved for cases when long VARCHARs are involved.
Tracker ticket CORE-2650

**Complete In Beta 2**

**SET BIND OF "type1" TO "type2" statement**

New session-management statement SET BIND defines data type coercion rules between server-side and client-side data types.

For full details, see SET BIND Statement in the Management Statements chapter.

Tracker ticket CORE-6287.

**SQL-level replication management**

ALTER DATABASE and CREATE/ALTER TABLE statements are extended to allow SQL-level management for the replicated table set and current replication state. For details, see Replication Management in the Data Definition Language chapter.

Tracker ticket CORE-6285.

**FLOAT datatype is now SQL standard compliant**

FLOAT(p) definition is changed to represent precision in binary digits (as defined by the SQL specification) rather than in decimal digits as before. For details, see Standard Compliance for Data Type FLOAT in the Data Definition Language chapter.

Tracker ticket CORE-6109.

**Starting multiple transactions using the same initial transaction snapshot**

SET TRANSACTION statement makes it possible to share the same transaction snapshot among multiple transactions (possibly started by different attachments). For details, see Sharing Transaction Snapshots in the Data Manipulation Language chapter.

Tracker ticket CORE-6018.

**Better transaction control in ISQL**

ISQL can now (optionally) remember the transaction parameters of the last started transaction and reuse them for subsequent transactions. For details, see Keeping Transaction Parameters in the Utilities chapter.

Tracker ticket CORE-4933.

**Lateral derived tables**

Support for SQL:2011 compliant lateral derived tables. For details, see Lateral Derived Tables in the Data Manipulation Language chapter.

Tracker ticket CORE-3435.

**Convenient usage of TIMESTAMP/TIME WITH TIME ZONE when appropriate ICU library is not installed on the client side**

In order to work with time zone names introduced with the new data types TIME WITH TIME ZONE
and \texttt{TIMESTAMP WITH TIME ZONE}, the Firebird client library provides API extensions that internally use the ICU library. If the ICU library is missing (or has an incorrect version), the time value would be represented in GMT which may be inconvenient.

To provide a better workaround to this issue, the so called \textit{EXTENDED} format of the time zone information has been introduced. It includes both time zone name and its corresponding GMT offset. The GMT offset will be used as a fallback in the case of missing or mismatched ICU library. For details see \texttt{SET BIND Statement} in the \textbf{Management Statements} chapter.

Tracker ticket \texttt{CORE-6286}.

\textbf{Options in user management statements can be specified in arbitrary order}

DDL statements \texttt{CREATE USER}, \texttt{RECREATE USER}, \texttt{ALTER USER}, \texttt{ALTER CURRENT USER} and \texttt{CREATE OR ALTER USER} now allow their options (\texttt{PASSWORD}, \texttt{FIRSTNAME}, \texttt{TAGS}, etc) to be specified in arbitrary order.

Tracker ticket \texttt{CORE-6279}.

\textbf{Efficient table scans for DBKEY-based range conditions}

Range conditions (less-than and more-than) applied to a \texttt{RDB$DB_KEY} pseudo-column are now executed using a range table scan instead of a full table scan, thus providing better performance of such queries.

Tracker ticket \texttt{CORE-6278}.

\textbf{Increased parsing speed of long queries}

Stack growth increment inside the SQL parser has been increased to allow less memory reallocations/copies and thus improve the parsing performance for long queries.

Tracker ticket \texttt{CORE-6274}.

\textbf{API methods to set various names (field, relation, etc.) in the metadata builder}

Methods \texttt{setField()}, \texttt{setRelation()}, \texttt{setOwner()}, \texttt{setAlias()} have been added to the \texttt{IMetadataBuilder} interface of the Firebird API to set up the corresponding values for the given API message.

Tracker ticket \texttt{CORE-6268}.

\textbf{SUSPEND is prohibited in procedures and EXECUTE BLOCK without RETURNS}

If a stored procedure or an \texttt{EXECUTE BLOCK} statement misses the \texttt{RETURNS} declaration (i.e. it has no output parameters), then the \texttt{SUSPEND} statement inside its body is prohibited and error \texttt{isc_suspend_without_returns} is raised.

Tracker ticket \texttt{CORE-6239}.

\textbf{Improve performance when using SRP plugin for authentication}

Connections cache has been implemented inside the SRP authentication plugin to improve the performance.

Tracker ticket \texttt{CORE-6237}. 
Delivery of key known to the client to any database connection

It makes it possible to run standard utilities (like \textit{gfix}) or service tasks against an encrypted database on remote server in the cases when the database key is known to the client.

Tracker ticket \texttt{CORE-6220}.

Support for specials (inf/nan) when sorting DECFLOAT values

Special values (like \textit{INF}/\textit{NaN}) have been taken into account when sorting DECFLOAT values, the output order is now consistent with their comparison rules.

Tracker ticket \texttt{CORE-6219}.

Extend trace record for COMMIT/ROLLBACK RETAINING to show old/new transaction IDs

\texttt{COMMIT/ROLLBACK RETAINING} statement preserves the current transaction context but generates a new transaction ID. The trace output has been extended to show this new transaction ID in the \texttt{COMMIT\_RETAINING} and \texttt{ROLLBACK\_RETAINING} trace events and also show both initial and new transaction IDs in every transaction identifier in the trace records.

Tracker ticket \texttt{CORE-6095}.

Show OS-specific error when entrypoint is not found in dynamic library

When the dynamic library loaded by the Firebird engine misses the required entrypoint, the reported error now includes the OS-specific information.

Tracker ticket \texttt{CORE-6069}.

Change behavior of skipped and repeated wall times within time zones

Within time zones, some wall times do not exist (DST starting) or repeat twice (DST ending). Firebird has been modified to handle these situations accordingly to the ECMAScript standard. For example:

- 1:30 AM on November 5, 2017 in America/New\_York is repeated twice (fall backward), but it must be interpreted as 1:30 AM UTC\(-\)04 instead of 1:30 AM UTC\(-\)05.
- 2:30 AM on March 12, 2017 in America/New\_York does not exist, but it must be interpreted as 2:30 AM UTC\(-\)05 (equivalent to 3:30 AM UTC\(-\)04).

Tracker ticket \texttt{CORE-6058}.

Built-in functions converting binary string to hexadecimal representation and vice versa

Functions \texttt{HEX\_ENCODE} and \texttt{HEX\_DECODE} have been added to convert between binary strings and their hexadecimal representations. See \texttt{HEX\_ENCODE()} and \texttt{HEX\_DECODE()} for their description.

Tracker ticket \texttt{CORE-6049}.

Ability to see the current state of database encryption

Column \texttt{MON\$CRYPT\_STATE} has been added to the table \texttt{MON\$DATABASE}. It has four possible states:

- 0 - not encrypted
- 1 - encrypted
• 2 - decryption is in progress
• 3 - encryption is in progress

Tracker ticket [CORE-6048].

DPB properties for DECFLOAT configuration

New DPB items have been added to the API that can be used to set up the DECFLOAT properties for the current attachment. See also Setting DECFLOAT Properties in the Management Statements chapter.

Tracker ticket [CORE-6032].

Transaction info item fb_info_tra_snapshot_number in the API

New TPB item fb_info_tra_snapshot_number has been added to the API that returns the snapshot number of the current transaction.

Tracker ticket [CORE-6017].

EXECUTE STATEMENT with excess parameters

Input parameters of EXECUTE STATEMENT command may be declared using the EXCESS prefix to indicate that they can be missing in the query text. See Excess parameters in EXECUTE STATEMENT in the Data Definition Language chapter for details.

Tracker ticket [CORE-5658].

Ability to backup/restore only tables defined via a command line argument (pattern)

New command-line switch -INCLUDE_DATA has been added to gbak, see Ability to Backup/Restore Only Specified Tables in the Utilities chapter.

Tracker ticket [CORE-5538].

RECREATE USER statement

New DDL statement RECREATE USER has been added to drop and re-create the specified user in a single step.

Tracker ticket [CORE-4726].

Authenticate user in "EXECUTE STATEMENT ON EXTERNAL DATA SOURCE" by hash of the current password

New sample plugin named ExtAuth has been added to the Firebird distribution package. It allows to omit user name and password when calling EXECUTE STATEMENT against a trusted group of servers sharing the same ExtAuth plugin and the key specific for that group. See /firebird/examples/extauth/INSTALL for more details.

Tracker ticket [CORE-3983].

Extended precision for numerics

Fixed point numerics with precision up to 38 digits are now supported, along with improved intermediate calculations for shorter numerics. For details, see Increased Precision for NUMERIC.
and DECIMAL Types in the Data Definition Language chapter.

**Complete In Beta 1**

**Support for international time zones**

International time zone support from Firebird 4.0 onward comprises data types, functions and internal algorithms to manage date/time detection, storage and calculations involving international time zones based on UTC (Adriano dos Santos Fernandes).

For full details, see Support for International Time Zones in the Engine chapter.

Tracker tickets CORE-694 and CORE-909

**Built-in replication**

Built-in logical (row level) replication, both synchronous and asynchronous (Dmitry Yemanov & Roman Simakov)

For details, see Firebird Replication in the Engine chapter.

Tracker ticket CORE-2021

**New way to capture the database snapshot**

Introducing a new methodology for the Firebird engine to capture the snapshots for retaining the consistency of a transaction's view of database state. The new approach enables read consistency to be maintained for the life of a statement in READ COMMITTED transactions and also allows more optimal garbage collection.

The changes are described in more detail in the topic Commit Order for Capturing the Database Snapshot in the chapter Changes in the Firebird Engine.

**Pooling of external connections**

The external data source (EDS) subsystem has been augmented by a pool of external connections. The pool retains unused external connections for a period to reduce unnecessary overhead from frequent connections and disconnections by clients using the same connection strings (Vlad Khorsun).

For details, see Pooling of External Connections in the Engine chapter.

Tracker ticket CORE-5990

**Physical standby solution**

Physical standby solution (incremental restore via nbackup).

The changes are described in more detail in the Utilities chapter in the topic nBackup: GUID-based Backup and In-Place Merge.

**Extended length of metadata identifiers**

Metadata names longer than 31 bytes: new maximum length of object names is 63 characters.

The changes are described in more detail in the topic Extended Length for Object Names in the
Configurable time-outs

Timeout periods configurable for statements, transactions and connections.

The changes for statements and connections are described in more detail in the topic Timeouts at Two levels in the chapter Changes in the Firebird Engine (Vlad Khorsun).

Tracker tickets CORE-658 and CORE-985

New DECFLOAT data type

The SQL:2016 standard-compliant high-precision numeric type DECFLOAT is introduced, along with related operational functions. It is described in detail in the topic Data type DECFLOAT in the chapter Data Definition Language.

Enhanced system privileges

Predefined system roles, administrative permissions.

The changes are described in more detail in the topic Enhanced System Privileges in the Security chapter.

See also the Management Statements chapter for some background about what the new system privileges are intended for.

GRANT ROLE TO ROLE

Granting roles to other roles, described in detail in the topic Granting a Role to Another Role in the Security chapter.

User groups

User groups and cumulative permissions are described in detail in the topic Granting a Role to Another Role in the Security chapter.

Batch operations in the API

Batch API operations, bulk load optimizations, support for passing BLOBs in-line.

Tracker ticket CORE-820

For details, see Support for Batch Insert and Update Operations in the API.

Window functions extensions

Extensions to window functions are described in detail in the Data Manipulation Language chapter in the topics Frames for Window Functions, Named Windows and More Window Functions.

FILTER Clause for Aggregate Functions

FILTER clause implemented for aggregate functions, see FILTER Clause for Aggregate Functions in the Data Manipulation Language chapter.

Tracker ticket CORE-5768
Enhanced RETURNING clause in DML to enable returning all current field values

Introduces the `RETURNING *` syntax, and variants, to return a complete set of field values after committing a row that has been inserted, updated or deleted (Adriano dos Santos Fernandes). For details, see `RETURNING * Now Supported` in the Data Manipulation Language chapter.

Tracker ticket CORE-3808

Built-in functions FIRST_DAY and LAST_DAY

New date/time functions `FIRST_DAY` and `LAST_DAY`, see Two New Date/Time Functions in the Data Manipulation Language chapter.

Tracker ticket CORE-5620

Built-in Cryptographic functions

New security-related functions, including eight cryptographic ones, see Built-in Cryptographic Functions in the Security chapter.

Tracker ticket CORE-5970

Monitoring Compression and Encryption Status of Attachments

Compression and encryption status of a connection are now available in the monitoring table `MON$ATTACHMENTS`:

- `MON$WIRE_COMPRESSED` (wire compression enabled = 1, disabled = 0)
- `MON$WIRE_ENCRYPTED` (wire encryption enabled = 1, disabled = 0)

Tracker ticket CORE-5536

Improve performance of `gbak restore`

The new Batch API was used to improve the performance of `gbak restore`, including parallel operations.

Tracker tickets CORE-2992 and CORE-5952

Backup and Restore with Encryption

Support for backing up and restoring encrypted databases using the crypt and keyholder plugins — see Backup and Restore with Encryption in the Utilities chapter.

Also available is compression and decompression of both encrypted and non-encrypted backups.

Compatibility with Older Versions

Notes about compatibility with older Firebird versions are collated in the “Compatibility Issues” chapter.
Chapter 3. Changes in the Firebird Engine

The Firebird engine, version 4, presents no radical changes in architecture or operation. Improvements and enhancements continue, including a doubling of the maximum database page size and the long-awaited ability to impose timeouts on connections and statements that could be troublesome, primary-replica replication and international time zone support.

Firebird 4 creates databases with the on-disk structure numbered 13—“ODS 13”. The remote interface protocol number is 16.

Maximum Page Size Increased To 32KB

Dmitry Yemanov

Tracker ticket CORE-2192

The maximum page size for databases created under ODS 13 has been increased from 16 KB to 32 KB.

External Functions (UDFs) Feature Deprecated

The original design of external functions (UDF) support has always been a source of security problems. The most dangerous security holes, that occurred when UDFs and external tables were used simultaneously, were fixed as far back as Firebird 1.5. Nevertheless, UDFs have continued to present vulnerability issues like server crashes and the potential to execute arbitrary code.

The use of UDFs has been aggressively deprecated in Firebird 4:

- The default setting for the configuration parameter UdfAccess is NONE. In order to run UDFs at all will now require an explicit configuration of Restrict UDF
- The UDF libraries (ib_udf, fbudf) are no longer distributed in the installation kits
- Most of the functions in the libraries previously distributed in the shared (dynamic) libraries ib_udf and fbudf had already been replaced with built-in functional analogs. A few remaining UDFs have been replaced with either analog routines in a new library of UDRs named udf_compat or converted to stored functions.

Refer to Deprecation of External Functions (UDFs) in the Compatibility chapter for details and instructions about upgrading to use the safe functions.

- Replacement of UDFs with UDRs or stored functions is strongly recommended

Support for International Time Zones

Adriano dos Santos Fernandes

Tracker tickets CORE-909 and CORE-694
Time zone support from Firebird 4.0 onward consists of

- data types TIME WITH TIME ZONE and TIMESTAMP WITH TIME ZONE; implicitly also TIME WITHOUT TIME ZONE and TIMESTAMP WITHOUT TIME ZONE as aliases for the existing types TIME and TIMESTAMP
- expressions and statements to work with time zones
- conversion between data types without/with time zones

The data types TIME WITHOUT TIME ZONE, TIMESTAMP WITHOUT TIME ZONE and DATE are defined to use the session time zone when converting from or to a TIME WITH TIME ZONE or TIMESTAMP WITH TIME ZONE. TIME and TIMESTAMP are synonymous to their respective WITHOUT TIME ZONE data types.

Session Time Zone

As the name implies, the session time zone, can be different for each database attachment. It can be set explicitly in the DPB or SPB with the item isc_dbp_session_time_zone; otherwise, by default, it uses the same time zone as the operating system of the Firebird server process. This default can be overridden in firebird.conf, see DefaultTimeZone setting in the Configuration Additions and Changes chapter.

Subsequently, the time zone can be changed to a given time zone using a SET TIME ZONE statement or reset to its original value with SET TIME ZONE LOCAL.

Time Zone Format

A time zone is a string, either a time zone region (for example, 'America/Sao_Paulo') or a displacement from GMT in hours:minutes (for example, '-03:00').

A time/timestamp with time zone is considered equal to another time/timestamp with time zone if their conversions to UTC are equivalent. For example, time '10:00 -02:00' and time '09:00 -03:00' are equivalent, since both are the same as time '12:00 GMT'.

The same equivalence applies in UNIQUE constraints and for sorting purposes.

Data Types for Time Zone Support

The syntax for declaring the data types TIMESTAMP and TIME has been extended to include arguments defining whether the field should be defined with or without time zone adjustments, i.e.,

```
TIME [ { WITHOUT | WITH } TIME ZONE ]
TIMESTAMP [ { WITHOUT | WITH } TIME ZONE ]
```

The default for both TIME and TIMESTAMP is WITHOUT TIME ZONE. For more details, see Data Type Extensions for Time Zone Support in the Data Definition Language chapter.
API Support for Time Zones

- Structures (structs)
- Functions

Time Zone Statements and Expressions

Additions and enhancements to syntax in DDL and DML are listed in this section. Follow the links indicated to the details in the DDL and DML chapters.

**Statement** `SET TIME_ZONE`

Changes the session time zone

**Expression** `AT`

Translates a time/timestamp value to its corresponding value in another time zone

**Expression** `EXTRACT`

Two new arguments have been added to the `EXTRACT` expression: `TIMEZONE_HOUR` and `TIMEZONE_MINUTE` to extract the time zone hours displacement and time zone minutes displacement, respectively.

**Expression** `LOCALTIME`

Returns the current time as a `TIME WITHOUT TIME ZONE`, i.e., in the session time zone

**Expression** `LOCALTIMESTAMP`

Returns the current timestamp as a `TIMESTAMP WITHOUT TIME ZONE`, i.e., in the session time zone

**Expressions** `CURRENT_TIME` and `CURRENT_TIMESTAMP`

In version 4.0, `CURRENT_TIME` and `CURRENT_TIMESTAMP` now return `TIME WITH TIME ZONE` and `TIMESTAMP WITH TIME ZONE`, with the time zone set by the session time zone

**Virtual table** `RDB$TIME_ZONES`

A virtual table listing time zones supported in the engine. Columns:

- `RDB$TIME_ZONE_ID` type `INTEGER`
- `RDB$TIME_ZONE_NAME` type `CHAR(63)`

**Package** `RDB$TIME_ZONE_UTIL`

A package of time zone utility functions and procedures:

**Function** `DATABASE_VERSION`

`RDB$TIME_ZONE_UTIL.DATABASE_VERSION` returns the version of the time zone database as a `VARCHAR(10)` `CHARACTER SET ASCII`.

**Example**
select rdb$time_zone_util.database_version() from rdb$database;

Returns:

DATABASE_VERSION
==============
2020d

**Procedure TRANSITIONS**

RDB$TIME_ZONE_UTIL.TRANSITIONS returns the set of rules between the start and end timestamps.

The input parameters are:

- **RDB$TIME_ZONE_NAME** type CHAR(63)
- **RDB$FROM_TIMESTAMP** type TIMESTAMP WITH TIME ZONE
- **RDB$TO_TIMESTAMP** type TIMESTAMP WITH TIME ZONE

Output parameters:

- **RDB$START_TIMESTAMP**
  - type TIMESTAMP WITH TIME ZONE — The start timestamp of the transition
- **RDB$END_TIMESTAMP**
  - type TIMESTAMP WITH TIME ZONE — The end timestamp of the transition
- **RDB$ZONE_OFFSET**
  - type SMALLINT — The zone’s offset, in minutes
- **RDB$DST_OFFSET**
  - type SMALLINT — The zone’s DST offset, in minutes
- **RDB$EFFECTIVE_OFFSET**
  - type SMALLINT — Effective offset (ZONE_OFFSET + DST_OFFSET)

**Example**

```sql
select *
from rdb$time_zone_util.transitions('America/Sao_Paulo',
  timestamp '2017-01-01',
  timestamp '2019-01-01');
```

Returns (RDB$ prefix left off for brevity):
### Updating the Time Zone Database

Time zones are often changed: of course, when it happens, it is desirable to update the time zone database as soon as possible.

Firebird stores \texttt{WITH TIME ZONE} values translated to UTC time. Suppose a value is created with one time zone database and a later update of that database changes the information in the range of our stored value. When that value is read, it will be returned as different to the value that was stored initially.

Firebird uses the \texttt{IANA time zone database} through the ICU library. The ICU library presented in the Firebird kit (Windows), or installed in a POSIX operating system, can sometimes have an outdated time zone database.

An updated database can be found on \texttt{this page on the FirebirdSQL GitHub}. Filename \texttt{le.zip} stands for little-endian and is the necessary file for most computer architectures (Intel/AMD compatible x86 or x64), while \texttt{be.zip} stands for big-endian architectures and is necessary mostly for RISC computer architectures. The content of the zip file must be extracted in the \texttt{/tzdata} sub-directory of the Firebird installation, overwriting existing \texttt{*\.res} files belonging to the database.

```
/tzdata is the default directory where Firebird looks for the time zone database. It can be overridden with the ICU\_TIMEZONE\_FILES\_DIR environment variable.
```

### Firebird Replication

Dmitry Yemanov; Roman Simakov

Tracker ticket \texttt{CORE-2021}

Firebird 4 introduces built-in support for uni-directional (“primary-replica”) logical replication. Logical here means record-level replication, as opposed to physical (page-level) replication. Implementation is primarily directed towards providing for high availability, but it can be used for other tasks as well.
Events that are tracked for replication include

- inserted/updated/deleted records
- sequence changes
- DDL statements

Replication is transactional and commit order is preserved. Replication can track changes either in all tables, or in a customized subset of tables. Any table that is to be replicated must have a primary key or, at least, a unique key.

**Replication Modes**

Both *synchronous* and *asynchronous* modes are available.

**Synchronous Mode**

In synchronous replication, the primary (master) database is permanently connected to the replica (slave) database(s) and changes are replicated immediately. Effectively the databases are in sync after every commit, which could have an impact on performance due to additional network traffic and round-trips.

> Although some recent uncommitted changes may be buffered, they are not transmitted until committed.

More than one synchronous replica can be configured, if necessary.

**Asynchronous Mode**

In asynchronous replication, changes are written into local journal files that are transferred over the wire and applied to the replica database. The impact on performance is much lower, but imposes a delay — *replication lag* — while changes wait to be applied to the replica database; i.e. the replica database is always “catching up” the master database.

**Access Modes**

There are two access modes for replica databases: *read-only* and *read-write*.

- With a read-only replica, only queries that do not modify data are allowed. Modifications are limited to the replication process only.

> Global temporary tables can be modified, as they are not replicated.

- A read-write replica allows execution of any query. In this access mode, potential conflicts must be resolved by users or database administrators.

**Journaling**

Asynchronous replication is implemented with journaling. Replicated changes are written into the journal which consists of multiple files, known as *replication segments*. The Firebird server writes
segments continuously, one after another. Every segment has a unique number which is generated sequentially. This number, known as a segment sequence, is combined with the database UUID to provide globally unique identification of journal segments. The global sequence counter is stored inside the replicated database and is reset only when the database is restored from backup.

Segments are rotated regularly, a process that is controlled by either maximum segment size or timeout. Both thresholds are configurable. Once the active segment reaches the threshold, it is marked as “full” and writing switches to the next available segment.

Full segments are archived and then reused for subsequent writes. Archiving consists of copying the segment in preparation for transferring it to the replica host and applying it there. Copying can be done by the Firebird server itself or, alternatively, by a user-specified custom command.

On the replica side, journal segments are applied in the replication sequence order. The Firebird server periodically scans for new segments appearing in the configured directory. Once the next segment is found, it gets replicated. For each replication source, the replication state is stored in a local file named for the UUID and the replication source. It contains markers for

- latest segment sequence (LSS)
- oldest segment sequence (OSS)
- a list of active transactions started between the OSS and the LSS

**About the LSS and OSS**

LSS refers to the last replicated segment. OSS refers to the segment that started the earliest transaction that was incomplete at the time LSS was processed.

These markers control two things:

1. what segment must be replicated next and
2. when segment files can be safely deleted

Segments with numbers between the OSS and the LSS are preserved in case the journal needs replaying after the replicator disconnects from the replica database; for example, due to a replication error or an idle timeout.

If there are no active transactions pending and the LSS was processed without errors, all segments up to and including the LSS are deleted.

If a critical error occurs, replication is temporarily suspended and will be retried after the timeout.

**Error Reporting**

All replication errors and warnings (such as detected conflicts) are written into the replication.log file. It may also include detailed descriptions of the operations performed by the replicator.

**Log file location**

The replication.log file is stored in the Firebird log directory. By default, the Firebird log directory is the root directory of the Firebird installation.
Setting Up Replication

Setup involves tasks on both the primary and replica sides.

Setting Up the Primary Side

Replication is configured using a single configuration file, replication.conf, on the host serving the primary database. Both global and per-database settings are possible within the same file. The available options are listed inside replication.conf, along with commented descriptions of each.

Per-database configurations

When configuring options at per-database level, the full database path must be specified within the {database} section. Aliases and wildcards are not accepted.

Inside the database, replication should be enabled using the following DDL statement:

```
ALTER DATABASE ENABLE PUBLICATION
```

Defining a Custom Replication Set

Optionally, the replication set (aka publication) should be defined. It includes tables that should be replicated. This is done using the following DDL statements:

```
-- to replicate all tables (including the ones created later)
ALTER DATABASE INCLUDE ALL TO PUBLICATION

-- to replicate specific tables
ALTER DATABASE INCLUDE TABLE T1, T2, T3 TO PUBLICATION
```

Tables may later be excluded from the replication set:

```
-- to disable replication of all tables (including the ones created later)
ALTER DATABASE EXCLUDE ALL FROM PUBLICATION

-- to disable replication of specific tables
ALTER DATABASE EXCLUDE TABLE T1, T2, T3 FROM PUBLICATION
```

Tables enabled for replication inside the database can be additionally filtered using two settings in replication.conf: include_filter and exclude_filter. They are regular expressions that are applied to table names, defining the rules for including or excluding them from the replication set. The regular expression syntax used to match table names is the same as in SIMILAR TO Boolean expressions.

Synchronous/Asynchronous Modes
Synchronous Mode
Synchronous replication can be turned on by setting the `sync_replica` specifying a connection string to the replica database, prefixed with username and password. Multiple entries are allowed.

In the SuperServer and SuperClassic architectures, the replica database is attached internally when the first user gets connected to the primary database and is detached when the last user disconnects from the primary database.

In the Classic Server architecture, each server process keeps its own active connection to the replica database.

Asynchronous Mode
For asynchronous replication the journaling mechanism must be set up. The primary parameter is `log_directory` which defines location of the replication journal. Specifying this location turns on asynchronous replication and tells the Firebird server to start producing the journal segments.

A Minimal Configuration
A minimal primary-side configuration would look like this:

```plaintext
database = /data/mydb.fdb
{
    log_directory = /dblogs/mydb/
    log_archive_directory = /shiplogs/mydb/
}
```

Archiving is performed by the Firebird server copying the segments from `/dblogs/mydb/` to `/shiplogs/mydb/`.

The same setup, but with user-defined archiving:

```plaintext
database = /data/mydb.fdb
{
    log_directory = /dblogs/mydb/
    log_archive_directory = /shiplogs/mydb/
    log_archive_command = "test ! -f $(archpathname) && cp $(logpathname) $(archpathname)"

$(archpathname)"
}
```

— where `$(logfile)` and `$(archpathname)` are built-in macros that are expanded to full path names when running the specified custom shell command.
About custom archiving

Custom archiving, through use of the setting log_archive_command allows use of any system shell command, including scripts or batch files, to deliver segments to the replica side. It could use compression, FTP, or whatever else is available on the server.

The actual transport implementation is up to the DBA: Firebird just produces segments on the primary side and expects them to appear at the replica side. If the replica storage can be remotely attached to the primary host, it becomes just a matter of copying the segment files. In other cases, some transport solution is required.

If custom archiving is used, the setting log_archive_directory can be omitted, unless log_archive_command mentions the $(archpathname) macro.

The same setup, with archiving performed every 10 seconds:

```
database = /data/mydb.fdb
{
  log_directory = /dblogs/mydb/
  log_archive_directory = /shiplogs/mydb/
  log_archive_command = "test ! -f $(archpathname) && cp $(logpathname) $(archpathname)"
  log_archive_timeout = 10
}
```

Read replication.conf for other possible settings.

**Applying the Primary Side Settings**

To take into effect changes applied to the primary-side settings, all users connected to a database must be disconnected (or a database must be shutdown). After that, all users connected again would use an updated configuration.

**Setting Up the Replica Side**

replication.conf file is also used for setting up the replica side. Setting the parameter log_source_directory specifies the location that the Firebird server scans for the transmitted segments. In addition, the DBA may specify explicitly which source database is accepted for replication, by setting the parameter source_guid.

**A Sample Replica Setup**

A configuration for a replica could looks like this:
database = /data/mydb.fdb
{
    log_source_directory = /incominglogs/
    source_guid = {6F9619FF-8B86-D011-B42D-00CF4FC964FF}
}

Read replication.conf for other possible settings.

Applying the Replica Side Settings

To take into effect changes applied to replica-side settings, the Firebird server must be restarted.

Creating a Replica Database

Task 1 — Make the initial replica

Any physical copying method can be used to create an initial replica of the primary database:

- File-level copy while the Firebird server is shut down
- ALTER DATABASE BEGIN BACKUP + file-level copy + ALTER DATABASE END BACKUP
- nbackup -l + file-level copy + nbackup -n
- nbackup -b 0 + nbackup -f -seq

Task 2 — Activate the replica access mode

Activating the access mode — for the copied database involves the command-line utility gfix with the new -replica switch and either read-only or read-write as the argument:

- To set the database copy as a read-only replica

  gfix -replica read-only <database>

If the replica is read-only then only the replicator connection can modify the database. This is mostly intended for high-availability solutions, as the replica database is guaranteed to match the primary one and can be used for fast recovery. Regular user connections may perform any operations allowed for read-only transactions: select from tables, execute read-only procedures, write into global temporary tables, etc. Database maintenance such as sweeping, shutdown, monitoring is also allowed.

A read-only replica can be useful for distributing read-only load, for example, analytics, away from the master database.

Read-only connections have the potential to conflict with replication if DDL statements that are performed on the master database are of the kind that requires an exclusive lock on metadata.

- To set the database copy as a read-write replica
gfix -replica read-write <database>

Read-write replicas allow both the replicator connection and regular user connections to modify the database concurrently. With this mode, there is no guarantee that the replica database will be in sync with the master one. Therefore, use of a read-write replica for high availability conditions is not recommended unless user connections on the replica side are limited to modifying only tables that are excluded from replication.

**Task 3 — Converting the replica to a regular database**

A third `gfix -replica` argument is available for “switching off” replication to a read-write replica when conditions call for replication flow to be discontinued for some reason. Typically, it would be used to promote the replica to become the primary database after a failure; or to make physical backup copies from the replica.

gfix -replica none <database>

**Pooling of External Connections**

Vlad Khorsun

Tracker ticket **CORE-5990**

To avoid delays when external connections are being established frequently, the external data source (EDS) subsystem has been augmented by a pool of external connections. The pool retains unused external connections for a period to reduce unnecessary overhead from frequent connections and disconnections by clients using the same connection strings.

**Key Characteristics of Connection Pooling**

The implementation of connection pooling in Firebird 4 eliminates the problem of interminable external connections by controlling and limiting the number of idle connections. The same pool is used for all external connections to all databases and all local connections handled by a given Firebird process. It supports a quick search of all pooled connections using four parameters, described below in **New Connections**.
Terminology

Two terms recur in the management of the connection pool, in configuration, by DDL ALTER statements during run-time and in new context variables in the SYSTEM namespace:

Connection life time
The time interval allowed from the moment of the last usage of a connection to the moment after which it will be forcibly closed. SQL parameter LIFETIME, configuration parameter ExtConnPoolLifeTime, context variable EXT_CONN_POOL_LIFETIME.

Pool size
The maximum allowed number of idle connections in the pool. SQL parameter SIZE, configuration parameter ExtConnPoolSize, context variable EXT_CONN_POOL_SIZE.

How the Connection Pool Works

Every successful connection is associated with a pool, which maintains two lists— one for idle connections and one for active connections. When a connection in the “active” list has no active requests and no active transactions, it is assumed to be “unused”. A reset of the unused connection is attempted using an ALTER SESSION RESET statement and,

• if the reset succeeds (no errors occur) the connection is moved into the “idle” list;
• if the reset fails, the connection is closed;
• if the pool has reached its maximum size, the oldest idle connection is closed.
• When the lifetime of an idle connection expires, it is deleted from the pool and closed.

New Connections

When the engine is asked to create a new external connection, the pool first looks for a candidate in the “idle” list. The search, which is case-sensitive, involves four parameters:

1. connection string
2. username
3. password
4. role

If suitable connection is found, it is tested to check that it is still alive.

• If it fails the check, it is deleted and the search is repeated, without reporting any error to the client
• Otherwise, the live connection is moved from the “idle” list to the “active” list and returned to the caller
• If there are multiple suitable connections, the most recently used one is chosen
• If there is no suitable connection, a new one is created and added to the “active” list.
Managing the Connection Pool

A new SQL statement has been introduced to manage the pool during run-time from any connection, between Firebird restarts, i.e., changes made with ALTER EXTERNAL CONNECTIONS POOL are not persistent.

This is the syntax pattern:

```sql
ALTER EXTERNAL CONNECTIONS POOL { <parameter variants> }
```

**Syntax Variants Available**

**ALTER EXTERNAL CONNECTIONS POOL SET SIZE <int>**
Sets the maximum number of idle connections

**ALTER EXTERNAL CONNECTIONS POOL SET LIFETIME <int> <time_part>**
Sets the lifetime of an idle connection, from 1 second to 24 hours. The `<time_part>` can be SECOND | MINUTE | HOUR.

**ALTER EXTERNAL CONNECTIONS POOL CLEAR ALL**
Closes all idle connections and instigates dissociation of all active connections so they are immediately closed when they become unused

**ALTER EXTERNAL CONNECTIONS POOL CLEAR OLDEST**
Closes expired idle connections

For a full descriptions and examples of the variants, see ALTER EXTERNAL CONNECTIONS POOL Statement in the chapter Management Statements.

**Querying the Connection Pool**

The state of the external connections pool can be queried using a set of new context variables in the 'SYSTEM' namespace:

- `EXT_CONN_POOL_SIZE` Pool size
- `EXT_CONN_POOL_LIFETIME` Idle connection lifetime, in seconds
- `EXT_CONN_POOL_IDLE_COUNT` Count of currently inactive connections
- `EXT_CONN_POOL_ACTIVE_COUNT` Count of active connections associated with the pool

**Parameters for Configuring the Connection Pool**

Two new parameters, for `firebird.conf` only, are for configuring the connection pool at process start. Follow the links for details.
**ExtConnPoolSize**

Configures the maximum number of idle connections allowed in the pool

**ExtConnPoolLifetime**

Configures the number of seconds a connection should stay available after it has gone idle

### Timeouts at Two levels

Vlad Khorsun

Tracker ticket [CORE-5488](#)

Firebird 4 introduces configurable timeouts for running SQL statements and for idle connections (sessions).

#### Idle Session Timeouts

An idle session timeout allows a user connection to close automatically after a specified period of inactivity. A database administrator can use it to enforce closure of old connections that have become inactive, to reduce unnecessary consumption of resources. It can also be used by application and tools developers as an alternative to writing their own modules for controlling connection lifetime.

By default, the idle timeout is not enabled. No minimum or maximum limit is imposed but a reasonably large period, such as a few hours, is recommended.

#### How the Idle Session Timeout Works

- When the user API call leaves the engine (returns to the calling connection) a special idle timer associated with the current connection is started
- When another user API call from that connection enters the engine, the idle timer is stopped and reset to zero
- If the maximum idle time is exceeded, the engine immediately closes the connection in the same way as with asynchronous connection cancellation:
  - all active statements and cursors are closed
  - all active transactions are rolled back
  - The network connection remains open at this point, allowing the client application to get the exact error code on the next API call. The network connection will be closed on the server side, after an error is reported or in due course as a result of a network timeout from a client-side disconnection.
Whenever a connection is cancelled, the next user API call returns the error `isc_att_shutdown` with a secondary error specifying the exact reason. Now, we have:

- `isc_att_shut_idle`
  - Idle timeout expired

  In addition to:

- `isc_att_shut_killed`
  - Killed by database administrator

- `isc_att_shut_db_down`
  - Database is shut down

- `isc_att_shut_engine`
  - Engine is shut down

### Setting the Idle Session Timeout

The idle timer will not start if the timeout period is set to zero.

An idle session timeout can be set:

- At database level, the database administrator can set the configuration parameter `ConnectionIdleTimeout`, an integer value in minutes. The default value of zero means no timeout is set. It is configurable per-database, so it may be set globally in `firebird.conf` and overridden for individual databases in `databases.conf` as required.

  The scope of this method is all user connections, except system connections (garbage collector, cache writer, etc.).

- At connection level, the idle session timeout is supported by both the API and a new SQL statement syntax. The scope of this method is specific to the supplied connection (attachment). Its value in the API is in seconds. In the SQL syntax it can be hours, minutes or seconds. Scope for this method is the connection to which it is applied.

### Determining the Timeout that is In Effect

The effective idle timeout value is determined whenever a user API call leaves the engine, checking first at connection level and then at database level. A connection-level timeout can override the value of a database-level setting, as long as the period of time for the connection-level setting is no longer than any non-zero timeout that is applicable at database level.
Take note of the difference between the time units at each level. At database level, in the conf file, the unit for SessionTimeout is minutes. In SQL, the default unit is minutes but can be expressed in hours or seconds explicitly. At the API level, the unit is seconds.

Absolute precision is not guaranteed in any case, especially when the system load is high, but timeouts are guaranteed not to expire earlier than the moment specified.

**SQL Syntax for Setting an Idle Session Timeout**

The statement for setting an idle timeout at connection level can run outside transaction control and takes effect immediately. The syntax pattern is as follows:

```
SET SESSION IDLE TIMEOUT value [{ HOUR | MINUTE | SECOND }]
```

If the time unit is not set, it defaults to MINUTE.

**Support at API Level**

Get/set idle connection timeout, seconds

```java
interface Attachment
    uint getIdleTimeout(Status status);
    void setIdleTimeout(Status status, uint timeOut);
```

The values of the idle connection timeout at both configuration and connection levels, along with the current actual timeout, can be obtained using the `isc_database_info()` API with some new info tags:

- `fb_info_ses_idle_timeout_db`
  Value set at config level

- `fb_info_ses_idle_timeout_att`
  Value set at given connection level

- `fb_info_ses_idle_timeout_run`
  Actual timeout value for the given connection, evaluated considering the values set at config and connection levels, see Determining the Timeout that is In Effect above.
Notes regarding remote client implementation

1. Attachment::setIdleTimeout() issues a “SET SESSION IDLE TIMEOUT” SQL statement

2. Attachment::getIdleTimeout() calls isc_database_info() with the fb_info_ses_idle_timeout_att tag

3. If the protocol of the remote Firebird server is less than 16, it does not support idle connection timeouts. If that is the case,
   - Attachment::setIdleTimeout() will return the error isc_wish_list
   - Attachment::getIdleTimeout() will return zero and set the isc_wish_list error
   - isc_database_info() will return the usual isc_info_error tag in the info buffer

Context Variable Relating to Idle Session Timeouts

The 'SYSTEM' context has a new variable: SESSION_IDLE_TIMEOUT. It contains the current value of idle connection timeout that was set at connection level, or zero, if no timeout was set.

Idle Session Timeouts in the Monitoring Tables

In MON$ATTACHMENTS:

MON$IDLE_TIMEOUT
   Connection-level idle timeout

MON$IDLE_TIMER
   Idle timer expiration time

MON$IDLE_TIMEOUT contains timeout value set at connection level, in seconds. Zero, if timeout is not set.

MON$IDLE_TIMER contains NULL if an idle timeout was not set or if a timer is not running.

Statement Timeouts

The statement timeout feature allows execution of a statement to be stopped automatically when it has been running longer than a given timeout period. It gives the database administrator an instrument for limiting excessive resource consumption from heavy queries.

Statement timeouts can also be useful to application developers when creating and debugging complex queries without advance knowledge of execution time. Testers and others could find them handy for detecting long-running queries and establishing finite run times for test suites.

How the Statement Timeout Works

When the statement starts execution, or a cursor is opened, the engine starts a special timer. It is stopped when the statement completes execution, or the last record has been fetched by the cursor.
A fetch does not reset this timer.

When the timeout point is reached:

- if statement execution is active, it stops at closest possible moment
- if statement is not active currently (between fetches, for example), it is marked as cancelled, and the next fetch will actually break execution and return an error

Statement types excluded from timeouts

Statement timeouts are not applicable to some types of statement and will simply be ignored:

- All DDL statements
- All internal queries issued by the engine itself

Setting a Statement Timeout

The timer will not start if the timeout period is set to zero.

A statement timeout can be set:

- at database level, by the database administrator, by setting the configuration parameter `StatementTimeout` in `firebird.conf` or `databases.conf`. `StatementTimeout` is an integer representing the number of seconds after which statement execution will be cancelled automatically by the engine. Zero means no timeout is set. A non-zero setting will affect all statements in all connections.

- at connection level, using the API and/or the new SQL statement syntax for setting a statement timeout. A connection-level setting (via SQL or the API) affects all statements for the given connection; units for the timeout period at this level can be specified to any granularity from hours to milliseconds.

- at statement level, using the API, in milliseconds

Determining the Statement Timeout that is In Effect

The statement timeout value that is in effect is determined whenever a statement starts executing, or a cursor is opened. In searching out the timeout in effect, the engine goes up through the levels, from statement through to database and/or global levels until it finds a non-zero value. If the value in effect turns out to be zero then no statement timer is running and no timeout applies.

A statement-level or connection-level timeout can override the value of a database-level setting, as long as the period of time for the lower-level setting is no longer than any non-zero timeout that is applicable at database level.
Take note of the difference between the time units at each level. At database level, in the conf file, the unit for `StatementTimeout` is seconds. In SQL, the default unit is seconds but can be expressed in hours, minutes or milliseconds explicitly. At the API level, the unit is milliseconds.

Absolute precision is not guaranteed in any case, especially when the system load is high, but timeouts are guaranteed not to expire earlier than the moment specified.

Whenever a statement times out and is cancelled, the next user API call returns the error `isc_cancelled` with a secondary error specifying the exact reason, viz.,

- `isc_cfg_stmt_timeout`: Config level timeout expired
- `isc_att_stmt_timeout`: Attachment level timeout expired
- `isc_req_stmt_timeout`: Statement level timeout expired

**Notes about Statement Timeouts**

1. A client application could wait longer than the time set by the timeout value if the engine needs to undo a large number of actions as a result of the statement cancellation
2. When the engine runs an `EXECUTE STATEMENT` statement, it passes the remainder of the currently active timeout to the new statement. If the external (remote) engine does not support statement timeouts, the local engine silently ignores any corresponding error.
3. When the engine acquires some lock from the lock manager, it tries to lower the value of the lock timeout using the remainder of the currently active statement timeout, if possible. Due to lock manager internals, any statement timeout remainder will be rounded up to whole seconds.

**SQL Syntax for Setting a Statement Timeout**

The statement for setting a statement execution timeout at connection level can run outside transaction control and takes effect immediately. The statement syntax pattern is:

```
SET STATEMENT TIMEOUT value [{ HOUR | MINUTE | SECOND | MILLISECOND }]
```

If the time part unit is not set, it defaults to SECOND.

**Support for Statement Timeouts at API Level**

Statement execution timeout at connection level, milliseconds:
interface Attachment
    uint getStatementTimeout(Status status);
    void setStatementTimeout(Status status, uint timeOut);

Get\set statement execution timeout at statement level, milliseconds:

interface Statement
    uint getTimeout(Status status);
    void setTimeout(Status status, uint timeOut);

Set statement execution timeout at statement level using ISC API, milliseconds:

ISC_STATUS ISC_EXPORT fb_dsql_set_timeout(ISC_STATUS*, isc_stmt_handle*, ISC_ULONG);

Getting the statement execution timeout at config and/or connection levels can be done using the isc_database_info() API function with some new info tags:

• fb_info_statement_timeout_db
• fb_info_statement_timeout_att

Getting the statement execution timeout at statement level can be done using the isc_dsql_info() API function with some new info tags:

isc_info_sql_stmt_timeout_user
    Timeout value of given statement

isc_info_sql_stmt_timeout_run
    Actual timeout value of given statement. Valid only for statements currently executing, i.e., when a timeout timer is actually running. Evaluated considering the values set at config, connection and statement levels, see Determining the Statement Timeout that is In Effect above.
Notes regarding remote client implementation

1. Attachment::setStatementTimeout() issues a “SET STATEMENT TIMEOUT” SQL statement
2. Attachment::getStatementTimeout() calls isc_database_info() with the fb_info_statement_timeout_att tag
3. Statement::setTimeout() saves the given timeout value and passes it with op_execute and op_execute2 packets
4. Statement::getTimeout() returns the saved timeout value
5. fb_dsql_set_timeout() is a wrapper over Statement::setTimeout()
6. If the protocol of the remote Firebird server is less than 16, it does not support statement timeouts. If that is the case,
   - “set” and “get” functions will return an isc_wish_list error
   - “info” will return the usual isc_info_error tag in the info buffer

Context Variable relating to Statement Timeouts

The 'SYSTEM' context has a new variable: STATEMENT_TIMEOUT. It contains the current value of the statement execution timeout that was set at connection level, or zero, if no timeout was set.

Statement Timeouts in the Monitoring Tables

In MON$ATTACHMENTS:

- **MON$STATEMENT_TIMEOUT**: Connection-level statement timeout

In MON$STATEMENTS:

- **MON$STATEMENT_TIMEOUT**: Statement-level statement timeout
- **MON$STATEMENT_TIMER**: Timeout timer expiration time

**MON$STATEMENT_TIMEOUT** contains timeout value set at connection or statement level, in milliseconds. Zero, if timeout is not set.

**MON$STATEMENT_TIMER** contains NULL if no timeout was set or if a timer is not running.

Support for Statement Timeouts in *isql*

A new command has been introduced in *isql* to enable an execution timeout in milliseconds to be set for the next statement. The syntax is:

```
SET LOCAL_TIMEOUT int-value
```

After statement execution, the timeout is automatically reset to zero.
Commit Order for Capturing the Database Snapshot

Nickolay Samofatov; Roman Simakov; Vlad Khorsun

Tracker ticket CORE-5953

Traditionally, a SNAPSHOT (“concurrency”) transaction takes a private copy of the transaction inventory page (TIP) at its start and uses it to refer to the state of the latest committed versions of all records in the database, right up until it commits or rolls back its own changes. Thus, by definition, a SNAPSHOT transaction sees the database state only as it was at the moment it started.

In the traditional model, a READ COMMITTED transaction does not use a stable snapshot view of database state and does not keep a private copy of the TIP. Instead, it asks the TIP for the most recent state of a record committed by another transaction. In Super (“SuperServer”) mode, the TIP cache is shared to provide optimal access to it by READ COMMITTED transactions.

The 'Commit Order' Approach

Firebird 4 takes a new approach to establishing a consistent view of the database state visible to running transactions. This new approach uses the concept of commit order.

It is sufficient to know the order of commits in order to capture the state of any transaction at the moment when a snapshot is created.

Commit Order for Transactions

The elements for establishing and utilising commit order are:

- Initialize a Commit Number (CN) for each database when the database is first opened
- Each time a transaction is committed, the Commit Number for that database is incremented and the new CN is associated with the specific transaction
- This specific transaction and commit number combination—“transaction CN” are stored in memory and can be queried subsequently while the database remains active
- A database snapshot is identified by the value stored for the global CN at moment when the database snapshot was created

Special Values for the Transaction CN

Possible values for the transaction Commit Number include some special CN values that signify whether the transaction is active or dead, viz.:

**CN_ACTIVE = 0**
- Transaction is active

**CN_PREHISTORIC = 1**
- Transaction was committed before the database started (i.e., older than OIT)
\textbf{CN\_PREHISTORIC} < \textbf{CN} < \textbf{CN\_DEAD}

Transaction was committed while the database was working

\textbf{CN\_DEAD} = \textbf{MAX\_TRA\_NUM} - 2

Dead transaction

\textbf{CN\_LIMBO} = \textbf{MAX\_TRA\_NUM} - 1

Transaction is in limbo

\textbf{The Rule for Record Visibility}

Supposing \textit{database snapshot} is the current snapshot in use by the current transaction and \textit{other transaction} is the transaction that created the given record version, the rule for determining the visibility of the record version works like this:

- If the state of \textit{other transaction} is 'active', 'dead' or 'in limbo' then the given record version is not visible to the current transaction
- If the state of \textit{other transaction} is 'committed' then the visibility of the given record version depends on the timing of the creation of \textit{database snapshot}, so
  - if it was committed before \textit{database snapshot} was created, it is visible to the current transaction;
  - if it was committed after \textit{database snapshot} was created, it is not visible to the current transaction.

Thus, as long as a maintained list of all known transactions with their associated Commit Numbers is in existence, it is enough to compare the CN of \textit{other transaction} with the CN of \textit{database snapshot} to decide whether the given record version should be visible within the scope of \textit{database snapshot}.

\begin{itemize}
\item The status of an association between a transaction and its CN can be queried using a new built-in function, \texttt{RDB\$GET\_TRANSACTION\_CN}.
\end{itemize}

\textit{SNAPSHOT} transactions now use the \textit{database snapshot} described above. Instead of taking a private copy of TIP when started it just remembers value of global Commit Number at that moment.

\textbf{Implementation details}

The list of all known transactions with associated Commit Numbers is maintained in shared memory. It is implemented as an array whose index is a transaction ID and its item value is the corresponding Commit Number.

The whole array is split into fixed-size blocks containing the CN's for all transactions between the OIT and Next Transaction markers. When Next Transaction moves out of the scope of the highest block, a new block is allocated. An old block is released when the OIT moves out of the scope of the lowest block.

\textbf{Block Size}

The default size of a TIP cache block is 4MB, providing capacity for 512 * 1024 transactions. It is
configurable in firebird.conf and databases.conf using the new parameter \texttt{TipCacheBlockSize}.

**Read Consistency for Statements in Read-Committed Transactions**

The existing implementation of READ COMMITTED isolation for transactions suffers from an important problem: a single statement, such as a \texttt{SELECT}, could see different views of the same data during execution.

For example, imagine two concurrent transactions, where the first inserts 1000 rows and commits, while the second runs \texttt{SELECT \texttt{COUNT(\texttt{\ast\texttt{)}}}} over the same table.

If the isolation level of the second transaction is READ COMMITTED, its result is hard to predict. It could be any of:

1. the number of rows in the table before the first transaction started, or
2. the number of rows in the table after the first transaction committed, or
3. any number between those two numbers.

Which of those results is actually returned depends on how the two transactions interact:

- CASE 1 would occur if the second transaction finished counting before the first transaction was committed, since the uncommitted inserts at that point are visible only to the first transaction.
- CASE 2 would occur if the second transaction started after the first had committed all of the inserts.
- CASE 3 occurs in any other combination of the conditions: the second transaction sees some, but not all, of the inserts during the commit sequence of the first transaction.

CASE 3 is the problem referred to as \textit{inconsistent read at the statement level}. It matters because, by definition, each \textit{statement} in a READ COMMITTED transaction has its own distinct view of database state. In the existing implementation, the statement’s view is not certain to remain stable for the duration of its execution: it could change between the start of execution and the completion.

Statements running in a SNAPSHOT transaction do not have this problem, since every statement runs against a consistent view of database state. Also, different statements that run within the same READ COMMITTED transaction could see different views of database state but this is “as designed” and is not a source of statement-level inconsistency.

**Solving the Inconsistent Read Problem**

See Tracker ticket \texttt{CORE-5954}.

The obvious solution to the inconsistent read problem is to have the read-committed transaction use a stable database snapshot during execution of a statement. Each new top-level statement creates its own database snapshot that sees the most recently committed data. With snapshots based on commit order, this is a very cheap operation. Let this snapshot be called a \textit{statement-level snapshot} for further references. Nested statements (triggers, nested stored procedures and functions, dynamic statements, etc.) use the same statement-level snapshot that was created by the top-level statement.
New Isolation Sub-Level for READ COMMITTED

A new sub-level for transactions in READ COMMITTED isolation is introduced: READ COMMITTED READ CONSISTENCY.

The existing sub-levels for READ COMMITTED isolation, namely RECORD VERSION and NO RECORD VERSION, are still supported and operate as before (without using statement-level snapshots), but they are now deprecated and may be removed in future Firebird versions.

In summary, the three variants for transactions in READ COMMITTED isolation are now:

- READ COMMITTED READ CONSISTENCY
- READ COMMITTED NO RECORD VERSION
- READ COMMITTED RECORD VERSION

Handling of Update Conflicts

When a statement executes in a READ COMMITTED READ CONSISTENCY transaction, its database view is retained in a fashion similar to a SNAPSHOT transaction. This makes it pointless to wait for the concurrent transaction to commit, in the hope of being able to read the newly-committed record version. So, when a READ COMMITTED READ CONSISTENCY transaction reads data, it behaves similarly to READ COMMITTED RECORD VERSION transaction: walks the back versions chain looking for a record version visible to the current snapshot.

When an update conflict occurs, the behaviour of a READ COMMITTED READ CONSISTENCY transaction is different to that of one in READ COMMITTED RECORD VERSION. The following actions are performed:

1. Transaction isolation mode is temporarily switched to READ COMMITTED NO RECORD VERSION.
2. A write-lock is taken for the conflicting record.
3. Remaining records of the current UPDATE/DELETE cursor are processed, and they are write-locked too.
4. Once the cursor is fetched, all modifications performed since the top-level statement was started are undone, already taken write-locks for every updated/deleted/locked record are preserved, all inserted records are removed.
5. Transaction isolation mode is restored to READ COMMITTED READ CONSISTENCY, new statement-level snapshot is created, and the top-level statement is restarted.

This algorithm ensures that already updated records remain locked after restart, they are visible to the new snapshot, and could be updated again with no further conflicts. Also, due to READ CONSISTENCY nature, the modified record set remains consistent.
Notes

- This restart algorithm is applied to UPDATE, DELETE, SELECT WITH LOCK and MERGE statements, with or without the RETURNING clause, executed directly by a client application or inside some PSQL object (stored procedure/function, trigger, EXECUTE BLOCK, etc).

- If an UPDATE/DELETE statement is positioned on some explicit cursor (using the WHERE CURRENT OF clause), then the step (3) above is skipped, i.e. remaining cursor records are not fetched and write-locked.

- If the top-level statement is selectable and update conflict happens after one or more records were returned to the client side, then an update conflict error is reported as usual and restart is not initiated.

- Restart does not happen for statements executed inside autonomous blocks (IN AUTONOMOUS TRANSACTION DO …).

- After 10 unsuccessful attempts the restart algorithm is aborted, all write locks are released, transaction isolation mode is restored to READ COMMITTED READ CONSISTENCY, and an update conflict error is raised.

- Any error not handled at step (3) above aborts the restart algorithm and statement execution continues normally.

- UPDATE/DELETE triggers fire multiple times for the same record if the statement execution was restarted and record is updated/deleted again.

- Statement restart is usually fully transparent to client applications and no special actions should be taken by developers to handle it in any way. The only exception is the code with side effects that are outside the transactional control, for example:
  - usage of external tables, sequences or context variables
  - sending e-mails using UDF
  - usage of autonomous transactions or external queries

- There is no way to detect whether a restart happened, but it could be done manually using code with side effects as described above, for example using a context variable.

- Due to historical reasons, error isc_update_conflict is reported as the secondary error code, with the primary error code being isc_deadlock.

Read Committed Read-Only Transactions

In the existing implementation, READ COMMITTED transactions in READ ONLY mode are marked as committed when the transaction starts. This provides a benefit in that record versions in such transactions are never “interesting”, thus not inhibiting the regular garbage collection and not delaying the advance of the OST marker.
**READ CONSISTENCY READ ONLY** transactions are still started as pre-committed, but in order to avoid the regular garbage collection breaking future statement-level snapshots, it delays the advance of the OST marker in the same way as it happens for **SNAPSHOT** transactions.

This delays only the *regular* (traditional) garbage collection, the *intermediate* garbage collection (see below) is not affected.

### Syntax and Configuration

Support for the new **READ COMMITTED READ CONSISTENCY** isolation level is found in SQL syntax, in the API and in configuration settings.

Where **SET TRANSACTION** is available in SQL, the new isolation sub-level is set as follows:

```
SET TRANSACTION READ COMMITTED READ CONSISTENCY
```

To start a **READ COMMITTED READ CONSISTENCY** transaction via the ISC API, use the new constant `isc_tpb_read_consistency` in the Transaction Parameter Buffer.

Starting with Firebird 4, usage of the legacy **READ COMMITTED** modes (**RECORD VERSION** and **NO RECORD VERSION**) is discouraged and **READ CONSISTENCY** mode is recommended to be used instead. For now, existing applications can be tested with the new **READ COMMITTED READ CONSISTENCY** isolation level by setting the new configuration parameter `ReadConsistency` described in the Configuration Additions and Changes chapter.

Please pay attention that the `ReadConsistency` configuration setting is enabled by default, thus forcing all **READ COMMITTED** transactions to be executed in the **READ CONSISTENCY** mode. Consider disabling this setting if the legacy behaviour of **READ COMMITTED** transactions must be preserved.

### Garbage Collection

The **record version visibility rule** provides the following logic for identifying record versions as garbage:

- If snapshot `CN` can see some record version (`RV_X`) then all snapshots with numbers greater than `CN` can also see `RV_X`.

- If all existing snapshots can see `RV_X` then all its back-versions can be removed, OR

- If the oldest active snapshot can see `RV_X` then all its back-versions can be removed.

The last part of the rule reproduces the legacy rule, whereby all record versions at the tail of the versions chain start from some “mature” record version. The rule allows that mature record version to be identified so that the whole tail after it can be cut.

However, with snapshots based on commit-order, version chains can be further shortened because it enables some record versions located in intermediate positions in the versions chain to be identified as eligible for GC. Each record version in the chain is marked with the value of the oldest
active snapshot that can see it. If several consecutive versions in a chain are marked with the same oldest active snapshot value, then all those following the first one can be removed.

The engine performs garbage collection of intermediate record versions during the following processes:

- sweep
- table scan during index creation
- background garbage collection in SuperServer
- in every user attachment after an updated or delete record is committed

Regular (traditional) garbage collection mechanism is not changed and still works the same way as in prior Firebird versions.

To make it work, the engine maintains in shared memory an array of all active database snapshots. When it needs to find the oldest active snapshot that can see a given record version, it just searches for the CN of the transaction that created that record version.

The default initial size of this shared memory block is 64KB but it will grow automatically when required. The initial block can be set to a custom size in firebird.conf and/or databases.conf using the new parameter SnapshotsMemSize.

Precision Improvement for Calculations Involving NUMERIC and DECIMAL

Alex Peshkov
Tracker ticket CORE-4409

As a side-effect of implementing the internal 128-bit integer data type, some improvements were made to the way Firebird handles the precision of intermediate results from calculations involving long NUMERIC and DECIMAL data types. In prior Firebird versions, numerics backed internally by the BIGINT data type (i.e. with precision between 10 and 18 decimal digits) were multiplied/divided using the same BIGINT data type for the result, which could cause overflow errors due to limited precision available. In Firebird 4, such calculations are performed using 128-bit integers, thus reducing possibilities for unexpected overflows.

Increased Number of Formats for Views

Adriano dos Santos Fernandes
Tracker ticket CORE-5647

Views are no longer limited to 255 formats (versions) before the database requires a backup and restore. The new limit is 32,000 versions.

This change does not apply to tables.
**Optimizer Improvement for GROUP BY**

Dmitry Yemanov

Tracker ticket CORE-4529

The improvement allows the use of a DESCENDING index on a column that is specified for GROUP BY.

**xinetd Support on Linux Replaced**

Alex Peshkov

Tracker ticket CORE-5238

On Linux, Firebird 4 uses the same network listener process (Firebird) for all architectures. For Classic, the main (listener) process now starts up via `init/systemd`, binds to the 3050 port and spawns a worker firebird process for every connection — similarly to what happens on Windows.

**Support for RISC v.64 Platform**

Richard Jones

Tracker ticket CORE-5779

A patch was introduced to compile Firebird 4.0 on the RISC v.64 platform.

**Virtual table RDB$CONFIG**

Vlad Khorsun

Tracker ticket CORE-3708

A virtual table enumerating configuration settings actual for the current database. Columns:

- **RDB$CONFIG_ID** type INTEGER
  - Unique row identifier, no special meaning
- **RDB$CONFIG_NAME** type VARCHAR(63)
  - Setting name (e.g. "TempCacheLimit")
- **RDB$CONFIG_VALUE** type VARCHAR(255)
  - Actual value of setting
- **RDB$CONFIG_DEFAULT** type VARCHAR(255)
  - Default value of setting (defined in the Firebird code)
- **RDB$CONFIG_IS_SET** type BOOLEAN
  - TRUE if value was set by user, FALSE otherwise
Table RDB$CONFIG is populated from in-memory structures upon request and its instance is preserved for the SQL query lifetime. For security reasons, access to this table is allowed to administrators only. Non-privileged users see no rows in this table (and no error is raised).
Chapter 4. Changes to the Firebird API and ODS

since Firebird 3.0 release

ODS (On-Disk Structure) Changes

New ODS Number

Firebird 4.0 creates databases with an ODS (On-Disk Structure) version of 13.

New System Tables

System tables added in ODS13:

- **RDB$TIME_ZONES**: Virtual table that enumerates supported time zones
- **RDB$PUBLICATIONS**: Publications defined in the database
- **RDB$PUBLICATION_TABLES**: Tables enabled for publication
- **RDB$CONFIG**: Virtual table that enumerates actual configuration settings

In Firebird 4.0, there’s a single (pre-defined) publication named RDB$DEFAULT. User-defined publications will be available in future Firebird releases.

New Columns in System Tables

Column RDB$SQL_SECURITY was added to the following system tables in ODS13:

- **RDB$DATABASE**
- **RDB$FUNCTIONS**
- **RDB$PACKAGES**
- **RDB$PROCEDURES**
- **RDB$RELATIONS**
- **RDB$TRIGGERS**

For RDB$DATABASE, it defines the default SQL SECURITY mode *(DEFINER* or *INVOKER*) applied to the newly created objects. For other system tables, it defines the SQL SECURITY mode active for the appropriate objects.

Also, column RDB$SYSTEM_PRIVILEGES is added to the system table RDB$ROLES. It stores system privileges granted to a role.
Application Programming Interfaces

The wire protocol version for the Firebird 4.0 API is 16. Additions and changes are described in the sections below.

Services Cleanup

Alex Peshkov

Apart from the widely-known Services Manager (service_mgr), Firebird has a group of so-called “version 1” service managers. Backup and gsec are examples, along with a number of other services related to shared cache control and the unused journaling feature. Since at least Firebird 3 they seem to be in a semi-working state at best, so they have undergone a cleanup.

A visible effect is that the constant service_mgr is no longer required in the connection string for a service request. The request call will ignore anything in that field, including an empty string. The remote client will do the right thing just by processing the host name, such as localhost:, inet://localhost/ or inet://localhost.

Services API Extensions

Support for nbackup -fixup

Alex Peshkov

Added support to fixup (i.e. change the physical backup mode to normal) databases after file-system copy.

The following action was added: isc_action_svc_nfix:: fixup database

Samples of use of new parameter in fbsvcmgr utility (supposing login and password are set using some other method):

fbsvcmgr -action_nfix dbname /tmp/ecopy.fdb

Timeouts for Sessions & Statements

Session Timeouts

See Support for Session Timeouts at API Level in the chapter Changes in the Firebird Engine.

Statement Timeouts

See Support for Statement Timeouts at API Level in the chapter Changes in the Firebird Engine.

New Isolation Sub-level for READ COMMITTED Transactions

Provides API support for the new READ COMMITTED READ CONSISTENCY isolation sub-level for READ COMMITTED transactions. To start a READ COMMITTED READ CONSISTENCY transaction via the ISC API, use the new constant isc_tpb_read_consistency in the Transaction Parameter Buffer.
Support for Batch Insert and Update Operations in the API

Alex Peshkov

The OO-API in Firebird 4 supports execution of statements with more than a single set of parameters—batch execution. The primary purpose of the batch interface design is to satisfy JDBC requirements for batch processing of prepared statements, but it has some fundamental differences:

- As with all data operations in Firebird, it is oriented on messages, not on single fields
- An important extension of our batch interface is support for inline use of BLOBs, which is especially efficient when working with small BLOBs
- The `execute()` method returns not a plain array of integers but the special `BatchCompletionState` interface which, depending on the batch creation parameters, can contain both the information about the updated records and the error flag augmented by detailed status vectors for the messages that caused execution errors

The methods described below illustrate how to implement everything needed for JDBC-style prepared statement batch operations. Almost all of the methods described are used in `11.batch.cpp`. Please refer to it to see a live example of batching in Firebird.

Creating a Batch

As with ResultSet a batch may be created in two ways—using either the Statement or the Attachment interface. In both cases, the `createBatch()` method of appropriate interface is called.

For the Attachment case, the text of the SQL statement to be executed in a batch is passed directly to `createBatch()`.

Tuning of the batch operation is performed using the Batch Parameters Block (BPB) whose format is similar to DPB v.2: beginning with the tag (IBatch::CURRENT_VERSION) and followed by the set of wide clumplets: 1-byte tag, 4-byte length, length-byte value. Possible tags are described in batch interface.

The recommended (and simplest) way to create a BPB for batch creation is to use the appropriate `XpbBuilder` interface:

```cpp
IXpbBuilder* pb = utl->getXpbBuilder(&status, IXpbBuilder::BATCH, NULL, 0);
pb->insertInt(&status, IBatch::RECORD_COUNTS, 1);
```

This usage of the BPB directs the batch to account for a number of updated records on per-message basis.

Creating the Batch Interface

To create the batch interface with the desired parameters, pass the BPB to a `createBatch()` call:
IBatch* batch = att->createBatch(&status, tra, 0, stmtText, SQL_DIALECT_V6, NULL, pb->getBufferLength(&status), pb->getBuffer(&status));

In this sample, the batch interface is created with the default message format because NULL is passed instead of the input metadata format.

**Getting the Message Format**

To proceed with the created batch interface, we need to get the format of the messages it contains, using the `getMetadata()` method:

```cpp
IMessageMetadata* meta = batch->getMetadata(&status);
```

If you have passed your own format for messages to the batch, of course you can simply use that.

We assume here that some function is present that can fill the buffer “data” according to the passed format “metadata”. For example,

```cpp
fillNextMessage(unsigned char* data, IMessageMetadata* metadata)
```

**A Message Buffer**

To work with the messages we need a buffer for our “data”:

```cpp
unsigned char* data = new unsigned char[meta->getMessageLength(&status)];
```

Now we can add some messages full of data to the batch:

```cpp
fillNextMessage(data, meta); batch->add(&status, 1, data); fillNextMessage(data, meta); batch->add(&status, 1, data);
```

An alternative way to work with messages is to use the `FB_MESSAGE` macro. An example of this method can be found in the batch interface example, `11.batch.cpp`.

**Executing the Batch**

The batch is now ready to be executed:

```cpp
IBatchCompletionState* cs = batch->execute(&status, tra);
```

We requested accounting of the number of modified records (inserted, updated or deleted) per
message. The interface BatchCompletionState is used to print it. The total number of messages processed by the batch could be less than the number of messages passed to the batch if an error happened and the option enabling multiple errors during batch processing was not turned on. To determine the number of messages processed:

```c
unsigned total = cs->getSize(&status);
```

Now to print the state of each message:

```c
for (unsigned p = 0; p < total; ++p)
    printf("Msg %u state %d\n", p, cs->getState(&status, p));
```

A complete example of printing the contents of BatchCompletionState is in the function `print_cs()` in sample 11.batch.cpp.

**Cleaning Up**

Once analysis of the completion state is finished, remember to dispose of it:

```c
cs->dispose();
```

If you want to empty the batch's buffers without executing it for some reason, such as preparing for a new portion of messages to process, use the `cancel()` method:

```c
batch->cancel(&status);
```

Being reference-counted, the batch does not have special method to close it—just a standard `release()` call:

```c
batch->release();
```

**Multiple Messages per Call**

More than a single message can be added in one call to the batch. It is important to remember that messages should be appropriately aligned for this feature to work correctly. The required alignment and aligned size of the message should be obtained from the interface MessageMetadata. For example:

```c
unsigned aligned = meta->getAlignedLength(&status);
```

Later that size will be useful when allocating an array of messages and working with it:
unsigned char* data = new unsigned char[aligned * N];
    // N is the desired number of messages
for (int n = 0; n < N; ++n) fillNextMessage(&data[aligned * n], meta);
batch->add(&status, N, data);

After that, the batch can be executed or the next portion of messages can be added to it.

**Passing In-line BLOBs in Batch Operations**

As a general rule, BLOBs are not compatible with batches. Batching is efficient when a lot of small data are to be passed to the server in single step. BLOBs are treated as large objects so, as a rule, it makes no sense to use them in batches.

Nevertheless, in practice it often happens that BLOBs are not too big. When that is the case, use of the traditional BLOB API (create BLOB, pass segments to the server, close BLOB, pass BLOB’s ID in the message) kills performance, especially over a WAN. Firebird’s batching therefore supports passing BLOBs to the server *in-line*, along with other messages.

**BLOB usage policy**

To use the in-line BLOB feature, first a *BLOB usage policy* has to be set up as an option in the BPB for the batch being created:

```cpp
    pb->insertInt(&status, IBatch::BLOB_IDS, IBatch::BLOB_IDS_ENGINE);
```

In this example, for the simplest and fairly common usage scenarios, the Firebird engine generates the temporary BLOB IDs needed to keep a link between a BLOB and the message where it is used. Imagine that the message is described as follows:

```cpp
    FB_MESSAGE(Msg, ThrowStatusWrapper,
        (FB_VARCHAR(5), id)
        (FB_VARCHAR(10), name)
        (FB_BLOB, desc)
    ) project(&status, master);
```

Something like the following will send a message to the server containing the BLOB:

```cpp
    project->id = ++idCounter;
    project->name.set(currentName);
    batch->addBlob(&status, descriptionSize, descriptionText, &project->desc);
    batch->add(&status, 1, project.getData());
```

**Over-sized BLOBs**

If some BLOB happens to be too big to fit into your existing buffer, then, instead of reallocating the buffer, you can use the `appendBlobData()` method to append more data to the last added BLOB:
batch->addBlob(&status, descriptionSize, descriptionText, &project->desc, bpbLength, bpb);

After adding the first part of the BLOB, get the next portion of data into descriptionText, update descriptionSize and then do:

batch->appendBlobData(&status, descriptionSize, descriptionText);

You can do this work in a loop but take care not to overflow the internal batch buffers. Its size is controlled by the BUFFER_BYTES_SIZE option when creating the batch interface. The default size is 10MB, but it cannot exceed 40MB. If you need to process a BLOB that is too big, having chosen to use batching on the basis of data involving a lot of small BLOBs, just use the standard BLOB API and the registerBlob method of the Batch interface.

**User-Supplied BLOB IDs**

Another possible choice in the BLOB policy is BLOB_IDS_USER, to supply a temporary BLOB_ID instead of having one generated by Firebird.

Usage is not substantially different. Before calling addBlob(), place the correct execution ID, which is unique per batch, into the memory referenced by the last parameter. Exactly the same ID should be passed in the data message for the BLOB.

Considering that generation of BLOB IDs by the engine is very fast, such a policy may seem useless. However, imagine a case where you get BLOBs and other data in relatively independent streams (blocks in a file, for example) and some good IDs are already present in them. Supplying the BLOB IDs can greatly simplify your code for such cases.

**Streams vs Segments**

Be aware that BLOBs created by the Batch interface are by default streamed, not segmented like BLOBs created by means of createBlob(). Segmented BLOBs provide nothing interesting compared with streamed ones—we support that format only for backward compatibility and recommend avoiding them in new development.

**Overriding to Use Segmented BLOBs**

If you really must have segmented BLOBs, you can override the default by calling:

batch->setDefaultBpb(&status, bpbLength, bpb);

Of course, the passed BPB could contain other BLOB creation parameters, too. You could also pass the BPB directly to addBlob() but, if most of the BLOBs you are going to add have the same non-default format, it is slightly more efficient to use setDefaultBpb().
A call to addBlob() will add the first segment to the BLOB; successive calls to appendBlobData() will add more segments.

**Segment size limit!**

Keep in mind that segment size is limited to 64KB - 1. Attempting to pass more data in a single call will cause an error.

**Multiple BLOBs Using Streams**

Using the method addBlobStream(), it is possible to add more than one BLOB to the batch in a single call.

A blob stream is a sequence of BLOBs, each starting with a BLOB header which needs to be appropriately aligned. The Batch interface provides a special call for this purpose:

```c
unsigned alignment = batch->getBlobAlignment(&status);
```

It is assumed that all components of a BLOB stream in a batch will be aligned, at least at the alignment boundary. This includes the size of stream portions passed to addBlobStream(), which should be a multiple of this alignment.

The header contains three fields: an 8-byte BLOB ID (must be non-zero), a 4-byte total BLOB size and a 4 byte BPB size. The total BLOB size includes the enclosed BPB, i.e. the next BLOB in the stream will always be found in the BLOB-size bytes after the header, taking the alignment into account.

The BPB is present if the BPB size is not zero and is placed immediately after the header. The BLOB data goes next, its format depending upon whether the BLOB is streamed or segmented:

- For a stream BLOB it is a plain sequence of bytes whose size is (BLOB-size - BPB-size)
- For a segmented BLOB, things are a bit more complicated: the BLOB data is a set of segments where each segment has the format: 2-bytes for the size of the segment, aligned at IBatch::BLOB_SEGHDR_ALIGN boundary, followed by as many bytes as are accounted for by this 2-byte segment size

**Bigger BLOBS in the Stream**

When a big BLOB is added to the stream, its size is not always known in advance. To avoid having too large a buffer for that BLOB (recalling that the size has to be provided in the BLOB header, before the BLOB data) a *BLOB continuation record* may be used. In the BLOB header, you leave BLOB size at a value known when creating that header and add a continuation record. The format of the continuation record is identical to the BLOB header, except that both the BLOB ID and the BPB size must always be zero.

Typically, you will want to have one continuation record per addBlobStream() call.

An example of this usage can be found in sample 11.batch.cpp.
Registering a Standard BLOB

The last method used to work with BLOBs stands apart from the first three that pass BLOB data inline with the rest of the batch data. It is required for registering in a batch the ID of a BLOB created using the standard BLOB API. This may be unavoidable if a really big BLOB has to be passed to the batch.

The ID of such BLOB cannot be used in the batch directly without causing an invalid BLOB ID error during batch execution. Instead do:

```c
batch->registerBlob(&status, &realId, &msg->desc);
```

If the BLOB policy is making the Firebird engine generate BLOB IDs then this code is enough to correctly register an existing BLOB in a batch. In other cases you will have to assign to `msg->desc` the ID that is correct from the point of view of the batch.

Batch Ops in the Legacy (ISC) API

A few words about access to batches from the ISC API: a prepared ISC statement can be executed in batch mode. The main support for it is present in ISC API functions: `fb_get_transaction_interface` and `fb_get_statement_interface`. These methods enable access to the appropriate interfaces in the same way as to existing ISC handles.

An example of this usage can be found in 12.batch_isc.cpp.

API Support for Time Zones

Structures (structs)

```c
struct ISC_TIME_TZ
{
    ISC_TIME utc_time;
    ISC_USHORT time_zone;
};

struct ISC_TIMESTAMP_TZ
{
    ISC_TIMESTAMP utc_timestamp;
    ISC_USHORT time_zone;
};
```
Chapter 4. Changes to the Firebird API and ODS

```
struct ISC_TIME_TZ_EX
{
    ISC_TIME utc_time;
    ISC_USHORT time_zone;
    ISC_SHORT ext_offset;
};

struct ISC_TIMESTAMP_TZ_EX
{
    ISC_TIMESTAMP utc_timestamp;
    ISC_USHORT time_zone;
    ISC_SHORT ext_offset;
};

API Functions: (FirebirdInterface.idl — IUtil interface)

void decodeTimeTz(
    Status status,
    const ISC_TIME_TZ* timeTz,
    uint* hours,
    uint* minutes,
    uint* seconds,
    uint* fractions,
    uint timeZoneBufferLength,
    string timeZoneBuffer
);

void decodeTimeStampTz(
    Status status,
    const ISC_TIMESTAMP_TZ* timeStampTz,
    uint* year,
    uint* month,
    uint* day,
    uint* hours,
    uint* minutes,
    uint* seconds,
    uint* fractions,
    uint timeZoneBufferLength,
    string timeZoneBuffer
);```
void encodeTimeTz(
    Status status,
    ISC_TIME_TZ* timeTz,
    uint hours,
    uint minutes,
    uint seconds,
    uint fractions,
    const string timeZone
);

void encodeTimeStampTz(
    Status status,
    ISC_TIMESTAMP_TZ* timeStampTz,
    uint year,
    uint month,
    uint day,
    uint hours,
    uint minutes,
    uint seconds,
    uint fractions,
    const string timeZone
);

void decodeTimeTzEx(
    Status status,
    const ISC_TIME_TZ_EX* timeTzEx,
    uint* hours,
    uint* minutes,
    uint* seconds,
    uint* fractions,
    uint timeZoneBufferLength,
    string timeZoneBuffer
);
void decodeTimeStampTzEx(
    Status status,
    const ISC_TIMESTAMP_TZ_EX* timeStampTzEx,
    uint* year,
    uint* month,
    uint* day,
    uint* hours,
    uint* minutes,
    uint* seconds,
    uint* fractions,
    uint timeZoneBufferLength,
    string timeZoneBuffer
);

API Support for DECFLOAT and Long Numerics

Alex Peshkov

DecFloat16 and DecFloat34 are helper interfaces that simplify working with the DECFLOAT (16-digit and 34-digit respectively) data types. Available methods in the DecFloat16 interface are the following:

void toBcd(
    const FB_DEC16* from,
    int* sign,
    uchar* bcd,
    int* exp
);

void toString(
    Status status,
    const FB_DEC16* from,
    uint bufferLength,
    string buffer
);

void fromBcd(
    int sign,
    const uchar* bcd,
    int exp,
    FB_DEC16* to
);
void fromString(
    Status status,
    const string from,
    FB_DEC16* to
);

The DecFloat34 interface shares the same methods, just using the FB_DEC34 structure.

Int128 is a helper interface for 128-bit integers (used internally as a base type for INT128, and also for NUMERIC and DECIMAL data types with precision > 18), it contains the following methods:

void toString(
    Status status,
    const FB_I128* from,
    int scale,
    uint bufferLength,
    string buffer
);

void fromString(
    Status status,
    int scale,
    const string from,
    FB_I128* to
);

Structures used by the aforementioned interfaces are defined below:

struct FB_DEC16
{
    ISC_UINT64 fb_data[1];
};

struct FB_DEC34
{
    ISC_UINT64 fb_data[2];
};

struct FB_I128
{
    ISC_UINT64 fb_data[2];
};
In order to work with these new interfaces, the `Util` interface has been extended with the following methods:

```cpp
DecFloat16 getDecFloat16(Status status);
DecFloat34 getDecFloat34(Status status);
Int128 getInt128(Status status);
```

### Additions to Other Interfaces

Alex Peshkov

A number of new methods have been added to the following interfaces.

**Attachment**

```cpp
uint getIdleTimeout(Status status);
void setIdleTimeout(Status status, uint timeOut);

uint getStatementTimeout(Status status);
void setStatementTimeout(Status status, uint timeOut);
```

**Batch**

```cpp
Batch createBatch(
    Status status,
    Transaction transaction,
    uint stmtLength,
    const string sqlStmt,
    uint dialect,
    MessageMetadata inMetadata,
    uint parLength,
    const uchar* par
);
```

**Statement**

```cpp
uint getTimeout(Status status);
void setTimeout(Status status, uint timeout);
```

```cpp
Batch createBatch(
    Status status,
    MessageMetadata inMetadata,
    uint parLength,
    const uchar* par
);
```
Chapter 4. Changes to the Firebird API and ODS

ClientBlock

AuthBlock getAuthBlock(Status status);

Server

void setDbCryptCallback(Status status, CryptKeyCallback cryptCallback);

MessageMetadata

uint getAlignment(Status status);
uint getAlignedLength(Status status);

MetadataBuilder

void setField(Status status, uint index, const string field);
void setRelation(Status status, uint index, const string relation);
void setOwner(Status status, uint index, const string owner);
void setAlias(Status status, uint index, const string alias);

FirebirdConf

uint getVersion(Status status);

ConfigManager

const string getDefaultSecurityDb();

Extensions to various getInfo() Methods

Attachment::getInfo()

The following actions were added:

<table>
<thead>
<tr>
<th>fb_info_protocol_version</th>
<th>Version of the remote protocol used by the current connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>fb_info_crypt_plugin</td>
<td>Name of the used database encryption plugin</td>
</tr>
<tr>
<td>fb_info_wire_crypt</td>
<td>Name of the connection encryption plugin</td>
</tr>
<tr>
<td>fb_info_statement_timeout_db</td>
<td>Statement execution timeout set in the configuration file</td>
</tr>
<tr>
<td>fb_info_statement_timeout_att</td>
<td>Statement execution timeout set at the connection level</td>
</tr>
<tr>
<td>Function Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fb_info_ses_idle_timeout_db</td>
<td>Idle connection timeout set in the configuration file</td>
</tr>
<tr>
<td>fb_info_ses_idle_timeout_att</td>
<td>Idle connection timeout set at the connection level</td>
</tr>
<tr>
<td>fb_info_ses_idle_timeout_run</td>
<td>Actual timeout value for the current connection</td>
</tr>
<tr>
<td>fb_info_creation_timestamp_tz</td>
<td>Database creation timestamp (with a time zone)</td>
</tr>
<tr>
<td>fb_info_features</td>
<td>List of features supported by provider of the current connection</td>
</tr>
<tr>
<td>fb_info_next_attachment</td>
<td>Current value of the next attachment ID counter</td>
</tr>
<tr>
<td>fb_info_next_statement</td>
<td>Current value of the next statement ID counter</td>
</tr>
<tr>
<td>fb_info_db_guid</td>
<td>Database GUID (persistent until restore / fixup)</td>
</tr>
<tr>
<td>fb_info_db_file_id</td>
<td>Unique ID of the database file at the filesystem level</td>
</tr>
<tr>
<td>fb_info_replica_mode</td>
<td>Database replica mode</td>
</tr>
</tbody>
</table>

Possible provider features (returned for fb_info_features) are:

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fb_feature_multi_statements</td>
<td>Multiple prepared statements in single attachment</td>
</tr>
<tr>
<td>fb_feature_multi_transactions</td>
<td>Multiple concurrent transaction in single attachment</td>
</tr>
<tr>
<td>fb_feature_named_parameters</td>
<td>Query parameters can be named</td>
</tr>
<tr>
<td>fb_feature_session_reset</td>
<td>ALTER SESSION RESET is supported</td>
</tr>
<tr>
<td>fb_feature_read_consistency</td>
<td>Read Consistency transaction isolation mode is supported</td>
</tr>
<tr>
<td>fb_feature_statement_timeout</td>
<td>Statement timeout is supported</td>
</tr>
<tr>
<td>fb_feature_statement_long_life</td>
<td>Prepared statements are not dropped on transaction end</td>
</tr>
</tbody>
</table>

Possible replica modes (returned for fb_info_replica_mode) are:

<table>
<thead>
<tr>
<th>Replica Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fb_info_replica_none</td>
<td>Database is not in the replica state</td>
</tr>
<tr>
<td>fb_info_replica_read_only</td>
<td>Database is a read-only replica</td>
</tr>
</tbody>
</table>
Statement::getInfo()

The following actions were added:

isc_info_sql_stmt_timeout_user     Timeout value of the current statement
isc_info_sql_stmt_timeout_run     Actual timeout value of the current statement
isc_info_sql_stmt_blob_align      Blob stream alignment in the Batch API

Transaction::getInfo()

The following action was added:

fb_info_tra_snapshot_number      Snapshot number of the current transaction

Additions to the Legacy (ISC) API

Alex Peshkov

A few functions have been added to the ISC API.

```
ISC_STATUS fb_get_transaction_interface(ISC_STATUS*, void*, isc_tr_handle*);
ISC_STATUS fb_get_statement_interface(ISC_STATUS*, void*, isc_stmt_handle*);
```

They can be used to get an OO API object from the corresponding ISC API handle.

Chapter 6. Configuration Additions and Changes

Parameters for Timeouts

Two new parameters are available for global and per-database configuration, respectively, of server-wide and database-wide idle session and statement timeouts. They are discussed in detail elsewhere (see links).

ConnectionIdleTimeout

The value is integer, expressing minutes. Study the notes on idle session timeouts carefully to understand how this configuration fits in with related settings via SQL and the API.

See Setting the Session Timeout in the chapter Changes in the Firebird Engine.

StatementTimeout

The value is integer, expressing seconds. Study the notes on statement timeouts carefully to understand how this configuration fits in with related settings via SQL and the API.

See Setting a Statement Timeout in the chapter Changes in the Firebird Engine.

Parameters for External Connection Pooling

These parameters enable customization of aspects of pooling external connections.

ExtConnPoolSize

Configures the maximum number of idle connections allowed in the pool. It is an integer, from 0 to 1000. The installation default is 0, which disables the connection pool.

ExtConnPoolLifetime

Configures the number of seconds a connection should stay available after it has gone idle. The installation default is 7200 seconds.

Parameters to Restrict Length of Object Identifiers

Object identifiers in an ODS 13 database can be up to 63 characters in length, and the engine stores them in UTF-8, not UNICODE_FSS as previously. Two new global or per-database parameters are available if you need to restrict either the byte-length or the character-length of object names in ODS 13 databases for some reason.

Longer object names are optional, of course. Reasons you might need to restrict their length could include:
• Constraints imposed by the client language interface of existing applications, such as gpre or Delphi

• In-house coding standards

• Interoperability for cross-database applications such as a third-party replication system or an in-house system that uses multiple versions of Firebird

This is not an exhaustive list. It is the responsibility of the developer to test usage of longer object names and establish whether length restriction is necessary.

Whether setting one or both parameters has exactly the same effect will depend on the characters you use. Any non-ASCII character requires 2 bytes or more in UTF-8, so one cannot assume that byte-length and character-length have a direct relationship in all situations.

The two settings are verified independently and if either constrains the length limit imposed by the other, use of the longer identifier will be disallowed.

If you set either parameter globally, i.e. in firebird.conf, it will affect all databases, including the security database. That has the potential to cause problems!

**MaxIdentifierByteLength**

Sets a limit for the number of bytes allowed in an object identifier. It is an integer, defaulting to 252 bytes, i.e., 63 characters * 4, 4 being the maximum number of bytes for each character.

To set it to the limit in previous Firebird versions, use 31.

**MaxIdentifierCharLength**

Sets a limit for the number of characters allowed in an object identifier. It is an integer, defaulting to 63, the new limit implemented in Firebird 4.

**Parameters Supporting Read Consistency in Transactions**

Firebird 4 takes a new approach to read consistency within transaction snapshots, enabling, amongst other benefits, a sustained consistent read for statements within READ COMMITTED transactions. This group of parameters allows for some customisation of the elements involved.

**ReadConsistency**

For now, existing applications can be tested with and without the new READ COMMITTED READ CONSISTENCY isolation level by setting this parameter. Possible values are 1 and 0.

**ReadConsistency = 1**

(Default) The engine ignores the specified [NO] RECORD VERSION sub-level and forces all read-committed transactions to be READ COMMITTED READ CONSISTENCY.
ReadConsistency = 0

Allows the legacy engine behaviour, with the RECORD VERSION and NO RECORD VERSION sub-levels working as before. READ COMMITTED READ CONSISTENCY is available but needs to be specified explicitly.

This behaviour can be defined in firebird.conf and/or databases.conf.

TipCacheBlockSize

The list of all known transactions with associated Commit Numbers is maintained in shared memory. It is implemented as an array whose index is a transaction ID and its item value is the corresponding Commit Number.

The whole array is split into fixed-size blocks containing the CN's for all transactions between the OIT and Next Transaction markers. When the “Next Transaction” marker moves out of the scope of the highest block, a new block is allocated. An old block is released when the “Oldest [Interesting] Transaction” (OIT) marker moves out of the scope of the lowest block.

The default size for a TIP cache block is 4MB, providing capacity for 512 * 1024 transactions. Use this parameter to configure a custom TIP cache block size in firebird.conf and/or databases.conf.

SnapshotsMemSize

To handle garbage collection of record versions younger than the Oldest Snapshot, (“intermediate record versions”) the engine maintains in shared memory an array that it can search for the Commit Number (CN) of a particular record version. See the Garbage Collection topic the chapter Changes in the Firebird Engine.

The default initial size of this shared memory block is 64KB but it will grow automatically when required. The initial block can be set to a custom size in firebird.conf and/or databases.conf.

Other Parameters

ClientBatchBuffer

Defines the buffer size used by the client connection for batch-mode transmission to the server (when Batch API is used). See the Support for Batch Insert and Update Operations in the API topic for more details.

DataTypeCompatibility

Specifies the compatibility level that defines what SQL data types can be exposed to the client API. Currently two options are available: "3.0" and "2.5". The "3.0" emulation mode hides data types introduced after Firebird 3.0 release, in particular DECIMAL/NUMERIC with precision 19 or higher, DECFLOAT, TIME/TIMESTAMP WITH TIME ZONE. The corresponding values are returned via data types already supported by Firebird 3.0. The "2.5" emulation mode also converts the BOOLEAN data type. See the Native to Legacy Coercion Rules table for details. This setting allows legacy client applications to work with Firebird 4.0 without recompiling and adjusting them to understand the
new data types.

**DefaultTimeZone**

Defines the time zone used when the client session does not specify it explicitly. If left empty, the default is the operating system time zone. When set at the server side, it's the default session time zone for attachments. When set at the client side, it's the default time zone used with client-side API functions.

**OutputRedirectionFile**

Allows to (optionally) redirect server's stdout/stderr streams to some user-defined file. By default, these streams are opened by the server but the output is discarded. Available as a global setting inside `firebird.conf`.

**Srp256 becomes the default authentication method**

See Tracker ticket [CORE-5788](#)

The Secure Remote Password authentication plugin now uses the SHA-256 algorithm to calculate the client's proof for both server and client sides (see `AuthServer` and `AuthClient` settings in `firebird.conf`). For backward compatibility, the client is configured to use the old Srp plugin (which implements the SHA-1 algorithm) as a fallback. This setup allows to communicate with Firebird 3 servers that are not configured to use Srp256 (available since v3.0.4).

**ChaCha is added as a default wire encryption method**

See Tracker ticket [CORE-5788](#)

`WireCryptPlugin` setting now defaults to ChaCha#20 as a wire encryption algorithm. If the appropriate plugin is missing, then Alleged RC4 (aka ARC4) algorithm is used.

**TempCacheLimit at database level**

See Tracker ticket [CORE-5718](#)

TempCacheLimit, for setting the maximum amount of temporary space that can be cached in memory, can now be configured at database level, i.e., in `databases.conf`. Previously, it was available only as a global setting for all databases.

**UseFileSystemCache is added as a replacement for FileSystemCacheThreshold**

See Tracker ticket [CORE-6332](#)

New boolean setting `UseFileSystemCache` provides an explicit control whether the OS filesystem cache is used for the database. The value is customizable at the database level. The old setting `FileSystemCacheThreshold` is preserved, but it is taken into account only if value for `UseFileSystemCache` is not specified explicitly. Setting `FileSystemCacheThreshold` becomes deprecated and will be removed in future Firebird versions.
**InlineSortThreshold**

See Tracker ticket **CORE-2650**

Controls how non-key fields are processed during sorting: stored inside the sort block or refetched from data pages after the sorting.

Historically, when the external sorting is performed, Firebird writes both key fields (those specified in the `ORDER BY` or `GROUP BY` clause) and non-key fields (all others referenced inside the query) to the sort blocks, either stored in memory or swapped to temporary files. Once the sorting is completed, these fields are read back from the sort blocks. This approach is generally considered being faster, because records are read in storage order instead of randomly fetching data pages corresponding to the sorted records. However, if non-key fields are large (e.g. long VARCHARs are involved), this increases the size of the sort blocks and thus causes earlier swapping and more I/O for temporary files. Firebird 4 provides an alternative approach, when only key fields and record `DBKEY`'s are stored inside the sort blocks and non-key fields are refetched from data pages after the sorting. This improves sorting performance in the case of longish non-key fields.

The value specified for `InlineSortThreshold` defines the maximum sort record size (in bytes) that can be stored inline, i.e. inside the sort block. Zero means that records are always refetched.
Chapter 7. Security

Security enhancements in Firebird 4 include:

**Enhanced System Privileges**

Alex Peshkov

Tracker ticket CORE-5343

This feature enables granting and revoking some special privileges for regular users to perform tasks that have been historically limited to SYSDBA only, for example:

- Run utilities such as `gbak`, `gfix`, `nbackup` and so on
- Shut down a database and bring it online
- Trace other users' attachments
- Access the monitoring tables
- Run management statements

The implementation defines a set of *system privileges*, analogous to object privileges, from which lists of privileged tasks can be assigned to roles.

**List of Valid System Privileges**

The following table lists the names of the valid system privileges that can be granted to and revoked from roles.

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_MANAGEMENT</td>
<td>Manage users</td>
</tr>
<tr>
<td>READ_RAW_PAGES</td>
<td>Read pages in raw format using Attachment::getInfo()</td>
</tr>
<tr>
<td>CREATE_USER_TYPES</td>
<td>Add/change/delete non-system records in RDB$TYPES</td>
</tr>
<tr>
<td>USE_NBACKUPUtility</td>
<td>Use nbackup to create database copies</td>
</tr>
<tr>
<td>CHANGE_SHUTDOWN_MODE</td>
<td>Shut down database and bring online</td>
</tr>
<tr>
<td>TRACE_ANY_ATTACHMENT</td>
<td>Trace other users' attachments</td>
</tr>
<tr>
<td>MONITOR_ANY_ATTACHMENT</td>
<td>Monitor (tables MON$) other users' attachments</td>
</tr>
<tr>
<td>ACCESS_SHUTDOWN_DATABASE</td>
<td>Access database when it is shut down</td>
</tr>
<tr>
<td>CREATE_DATABASE</td>
<td>Create new databases (given in security.db)</td>
</tr>
<tr>
<td>DROP_DATABASE</td>
<td>Drop this database</td>
</tr>
<tr>
<td>USE_GBAK_UTILITY</td>
<td>Use appropriate utility</td>
</tr>
<tr>
<td>USE_GSTAT_UTILITY</td>
<td>...</td>
</tr>
<tr>
<td>USE_GFIX_UTILITY</td>
<td>...</td>
</tr>
</tbody>
</table>
New Grantee Type SYSTEM PRIVILEGE

At a lower level, a new grantee type SYSTEM PRIVILEGE enables the SYSDBA to grant and revoke specific access privileges on database objects to a named system privilege. For example,

```
GRANT ALL ON PLG$SRP_VIEW TO SYSTEM PRIVILEGE USER_MANAGEMENT
```

grants to users having USER_MANAGEMENT privilege all rights to the view that is used in the SRP user management plug-in.

Assigning System Privileges to a Role

To put all this to use, we have some new clauses in the syntax of the `CREATE ROLE` and `ALTER ROLE` statements for attaching a list of the desired system privileges to a new or existing role.

The SET SYSTEM PRIVILEGES Clause

Tracker ticket CORE-2557

The syntax pattern for setting up or changing these special roles is as follows:

```sql
CREATE ROLE name SET SYSTEM PRIVILEGES TO <privilege1> {, <privilege2> {, ... <privilegeN> }}
ALTER ROLE name SET SYSTEM PRIVILEGES TO <privilege1> {, <privilege2> {, ... <privilegeN> }}
```

Both statements assign a non-empty list of system privileges to role `name`. The `ALTER ROLE` statement clears privileges previously assigned to the named role, before constructing the new list.
Be aware that each system privilege provides a very thin level of control. For some tasks it may be necessary to give the user more than one privilege to perform some task. For example, add `IGNORE_DB_TRIGGERS` to `USE_GSTAT UTILITY` because `gstat` needs to ignore database triggers.

Note that this facility provides a solution to an old Tracker request (CORE-2557) to implement permissions on the monitoring tables:

```
CREATE ROLE MONITOR SET SYSTEM PRIVILEGES TO MONITOR_ANY_ATTACHMENT;
GRANT MONITOR TO ROLE MYROLE;
```

**Dropping System Privileges from a Role**

This statement is used to clear the list of system privileges from the named role:

```
ALTER ROLE name DROP SYSTEM PRIVILEGES
```

The role `name` is not dropped, just the list of system privileges attached to it.

**Function RDB$SYSTEM_PRIVILEGE**

To accompany all this delegation of power is a new built-in function, `RDB$SYSTEM_PRIVILEGE()`. It takes a valid system privilege as an argument and returns True if the current attachment has the given system privilege.

**Syntax**

```
RDB$SYSTEM_PRIVILEGE( <privilege> )
```

**Example**

```
select rdb$system_privilege(user_management) from rdb$database;
```

**Granting a Role to Another Role**

Roman Simakov

Tracker ticket CORE-1815

Firebird 4 allows a role to be granted to another role—a phenomenon that has been nicknamed “cumulative roles”. If you hear that term, it is referring to roles that are embedded within other roles by way of `GRANT ROLE a TO ROLE b`, something Firebird would not allow before.

Take careful note that the `GRANT ROLE` syntax has been extended, along with its effects.
Syntax Pattern

```
GRANT [DEFAULT] role_name TO [USER | ROLE] user/role_name [WITH ADMIN OPTION];
REVOKE [DEFAULT] role_name FROM [USER | ROLE] user/role_name [WITH ADMIN OPTION];
```

Above syntax is a simplified version, the full GRANT and REVOKE has more options.

The DEFAULT Keyword

If the optional DEFAULT keyword is included, the role will be used every time the user logs in, even if the role is not specified explicitly in the login credentials. During attachment, the user will get the privileges of all roles that have been granted to him/her with the DEFAULT property. This set will include all the privileges of all the embedded roles that have been granted to the `role_name` role with the DEFAULT property.

Setting (or not setting) a role in the login does not affect the default role. The set of rights, given (by roles) to the user after login is the union of the login role (when set), all default roles granted to the user and all roles granted to this set of roles.

WITH ADMIN OPTION Clause

If a user is to be allowed to grant a role to another user or to another role, the WITH ADMIN OPTION should be included. Subsequently, the user will be able to grant any role in the sequence of roles granted to him, provided every role in the sequence has WITH ADMIN OPTION.

Example Using a Cumulative Role

```
CREATE DATABASE 'LOCALHOST:/TMP/CUMROLES.FDB';
CREATE TABLE T(I INTEGER);
CREATE ROLE TINS;
CREATE ROLE CUMR;
GRANT INSERT ON T TO TINS;
GRANT DEFAULT TINS TO CUMR WITH ADMIN OPTION;
GRANT CUMR TO USER US WITH ADMIN OPTION;
CONNECT 'LOCALHOST:/TMP/CUMROLES.FDB' USER 'US' PASSWORD 'PAS';
INSERT INTO T VALUES (1);
GRANT TINS TO US2;
```

Revoking the DEFAULT Property of a Role Assignment

To remove the DEFAULT property of a role assignment without revoking the role itself, include the DEFAULT keyword in the REVOKE statement:

```
REVOKE DEFAULT ghost FROM USER henry
REVOKE DEFAULT ghost FROM ROLE poltergeist
```
Otherwise, revoking a role altogether from a user is unchanged. However, now a role can be revoked from a role. For example,

```sql
REVOKE ghost FROM USER henry
REVOKE ghost FROM ROLE poltergeist
```

**Function RDB$ROLE_IN_USE**

Roman Simakov

Tracker ticket CORE-2762

A new built-in function lets the current user check whether a specific role is available under his/her current credentials. It takes a single-quoted role name as a string argument of arbitrary length and returns a Boolean result.

**Syntax**

```
RDB$ROLE_IN_USE(role_name)
```

**List Currently Active Roles**

Tracker ticket CORE-751

To get a list of currently active roles you can run:

```
SELECT * FROM RDB$ROLES WHERE RDB$ROLE_IN_USE(RDB$ROLE_NAME)
```

**SQL SECURITY Feature**

Roman Simakov

Tracker ticket CORE-5568

This new feature in Firebird 4 enables executable objects (triggers, stored procedures, stored functions) to be defined to run in the context of an SQL SECURITY clause, as defined in the SQL standards (2003, 2011).

The SQL SECURITY scenario has two contexts: `INVOKER` and `DEFINER`. The `INVOKER` context corresponds to the privileges available to the `CURRENT_USER` or the calling object, while `DEFINER` corresponds to those available to the owner of the object.

The SQL SECURITY property is an optional part of an object’s definition that can be applied to the object with DDL statements. The property cannot be dropped from functions, procedures and packages, but it can be changed from `INVOKER` to `DEFINER` and vice versa.

It is not the same thing as SQL privileges, which are applied to users and some database object
types to give them various types of access to database objects. When an executable object in Firebird needs access to a table, a view or another executable object, the target object is not accessible if the invoker does not have the necessary privileges on it. That has been the situation in previous Firebird versions and remains so in Firebird 4. That is, by default, all executable objects have the SQL SECURITY INVOKER property in Firebird 4. Any caller lacking the necessary privileges will be rejected.

If a routine has the SQL SECURITY DEFINER property applied to it, the invoking user or routine will be able to execute it if the required privileges have been granted to its owner, without the need for the caller to be granted those privileges specifically.

In summary:

- If INVOKER is set, the access rights for executing the call to an executable object are determined by checking the current user’s active set of privileges
- If DEFINER is set, the access rights of the object owner will be applied instead, regardless of the current user’s active privilege set

Syntax Patterns

```
CREATE TABLE table_name (...) [SQL SECURITY {DEFINER | INVOKER}]
ALTER TABLE table_name ... [{ALTER SQL SECURITY {DEFINER | INVOKER} | DROP SQL SECURITY}]
CREATE [OR ALTER] FUNCTION function_name ... [SQL SECURITY {DEFINER | INVOKER}] AS ...
CREATE [OR ALTER] PROCEDURE procedure_name ... [SQL SECURITY {DEFINER | INVOKER}] AS ...
CREATE [OR ALTER] TRIGGER trigger_name ... [SQL SECURITY {DEFINER | INVOKER} | DROP SQL SECURITY] [AS ...]
CREATE [OR ALTER] PACKAGE package_name [SQL SECURITY {DEFINER | INVOKER}] AS ...
ALTER DATABASE SET DEFAULT SQL SECURITY {DEFINER | INVOKER}
```

Packaged Routines

An explicit SQL SECURITY clause is not valid for procedures and functions defined in a package and will cause an error.

Triggers

Triggers inherit the setting of the SQL SECURITY property from the table, but it can be overridden explicitly. If the property is changed for a table, triggers that do not carry the overridden property will not see the effect of the change until next time the trigger is loaded into the metadata cache.

To remove an explicit SQL SECURITY option from a trigger, e.g. one named tr_ins, you can run

```
alter trigger tr_ins DROP SQL SECURITY;
```

To set it again to SQL SECURITY INVOKER, run
Examples Using the SQL SECURITY Property

1. With `DEFINER` set for table `t`, user `US` needs only the `SELECT` privilege on `t`. If it were set for `INVOKER`, the user would also need the `EXECUTE` privilege on function `f`.

   ```sql
   set term ^;
   create function f() returns int
   as
      begin
         return 3;
      end^;
   set term ;^;
   create table t (i integer, c computed by (i + f())) SQL SECURITY DEFINER;
   insert into t values (2);
   grant select on table t to user us;
   commit;

   connect 'localhost:/tmp/7.fdb' user us password 'pas';
   select * from t;
   
   set term ^;
   create function f (i integer) returns int SQL SECURITY DEFINER
   as
      begin
         insert into t values (:i);
         return i + 1;
      end^;
   set term ;^;
   grant execute on function f to user us;
   commit;

   connect 'localhost:/tmp/59.fdb' user us password 'pas';
   select f(3) from rdb$database;
   
   set term ^;
   create function f (i integer) returns int SQL SECURITY DEFINER
   as
      begin
         insert into t values (:i);
         return i + 1;
      end^;
   set term ;^;
   grant execute on function f to user us;
   commit;

   connect 'localhost:/tmp/59.fdb' user us password 'pas';
   select f(3) from rdb$database;
   ```

2. With `DEFINER` set for function `f`, user `US` needs only the `EXECUTE` privilege on `f`. If it were set for `INVOKER`, the user would also need the `INSERT` privilege on table `t`.

3. With `DEFINER` set for procedure `p`, user `US` needs only the `EXECUTE` privilege on `p`. If it were set for `INVOKER`, either the user or the procedure would also need the `INSERT` privilege on table `t`. 
set term ^;
create procedure p (i integer) SQL SECURITY DEFINER
as
begin
  insert into t values (:i);
end^
set term ;^

grant execute on procedure p to user us;
commit;

connect 'localhost:/tmp/17.fdb' user us password 'pas';
execute procedure p(1);

4. With *DEFINER* set for trigger tr_ins, user US needs only the INSERT privilege on tr. If it were set for *INVOKER*, either the user or the trigger would also need the INSERT privilege on table t.

create table tr (i integer);
create table t (i integer);
set term ^;
create trigger tr_ins for tr after insert SQL SECURITY DEFINER
as
begin
  insert into t values (NEW.i);
end^
set term ;^
grant insert on table tr to user us;
commit;

connect 'localhost:/tmp/29.fdb' user us password 'pas';
insert into tr values(2);

The result would be the same if SQL SECURITY *DEFINER* were specified for table TR:
create table tr (i integer) SQL SECURITY DEFINER;
cREATE TABLE T (I INTEGER);
SET TERM ^;
cREATE TRIGGER TR_INS FOR TR AFTER INSERT
AS
BEGIN
    INSERT INTO T VALUES (NEW.I);
END ^
SET TERM ;^
GRANT INSERT ON TABLE TR TO USER US;
COMMIT;
CONNECT 'LOCALHOST:/TMP/29.FDB' USER US PASSWORD 'PAS';
INSERT INTO TR VALUES(2);

5. With *DEFINER* set for package *pk*, user *US* needs only the EXECUTE privilege on *pk*. If it were set for *INVOKER*, either the user or the package would also need the INSERT privilege on table *t*.

create table t (i integer);
set term ^;
create package pk SQL SECURITY DEFINER
as
begin
    function f(i integer) returns int;
end ^
create package body pk
as
begin
    function f(i integer) returns int
    as
    begin
        insert into t values (:i);
        return i + 1;
    end
end ^
set term ;^
grant execute on package pk to user us;
COMMIT;
CONNECT 'LOCALHOST:/TMP/69.FDB' USER US PASSWORD 'PAS';
SELECT PK.F(3) FROM RDB$DATABASE;
Built-in Cryptographic Functions

Alex Peshkov

Tracker ticket CORE-5970

Firebird 4 introduces eight new built-in functions supporting cryptographic tasks.

**ENCRYPT() and DECRYPT()**

For encrypting/decrypting data using a symmetric cipher.

**Syntax**

```
{ENCRYPT | DECRYPT} ( <string | blob> USING <algorithm> [MODE <mode>] KEY <string> [IV <string>] [<endianness>] [CTR_LENGTH <smallint>] [COUNTER <bigint>])
```

- `<algorithm>` ::= { <block_cipher> | <stream_cipher> }
- `<block_cipher>` ::= { AES | ANUBIS | BLOWFISH | KHAZAD | RC5 | RC6 | SAFER+ | TWOFISH | XTEA }
- `<stream_cipher>` ::= { CHACHA20 | RC4 | SOBER128 }
- `<mode>` ::= { CBC | CFB | CTR | ECB | OFB }
- `<endianness>` ::= { CTR_BIG_ENDIAN | CTR_LITTLE_ENDIAN }

- Mode should be specified for block ciphers
- Initialization vector (IV) should be specified for block ciphers in all modes except ECB and all stream ciphers except RC4
- Endianness may be specified only in CTR mode, default is little endian counter
- Counter length (CTR_LENGTH, bytes) may be specified only in CTR mode, default is the size of IV
- Initial counter value (COUNTER) may be specified only for CHACHA20 cipher, default is 0
- Sizes of data strings passed to these functions are in accordance with the selected algorithm and mode requirements
- Functions return BLOB when the first argument is blob and varbinary for all text types.

**Examples**

```
select encrypt('897897' using sober128 key 'AbcdAbcdAbcdAbcd' iv '01234567')
from rdb$database;
select decrypt(x'0154090759DF' using sober128 key 'AbcdAbcdAbcdAbcd' iv '01234567')
from rdb$database;
select decrypt(secret_field using aes mode ofb key '0123456701234567' iv init_vector)
from secure_table;
```
**RSA_PRIVATE()**

Returns an RSA private key of specified length (in bytes) in PKCS#1 format as a VARBINARY string.

**Syntax**

```sql
RSA_PRIVATE ( <smallint> )
```

**Example**

```sql
select rdb$set_context('USER_SESSION', 'private_key', rsa_private(256))
from rdb$database;
```

Putting private keys in the context variables is not secure. SYSDBA and users with the role RDB$ADMIN or the system privilege MONITOR_ANY_ATTACHMENT can see all context variables from all attachments.

**RSA_PUBLIC()**

Returns the RSA public key for a specified RSA private key. Both keys are in PKCS#1 format.

**Syntax**

```sql
RSA_PUBLIC ( <private key> )
```

**Example**

```sql
select rdb$set_context('USER_SESSION', 'public_key',
    rsa_public(rdb$get_context('USER_SESSION', 'private_key'))) from rdb$database;
```

Run your samples one by one from the RSA_PRIVATE function forward.

**RSA_ENCRYPT()**

Pads data using **OAEP padding** and encrypts it using an RSA public key. Normally used to encrypt short symmetric keys which are then used in block ciphers to encrypt a message.

**Syntax**

```sql
RSA_ENCRYPT ( <string> KEY <public key> [LPARAM <string>] [HASH <hash>])
```

**Example**

```sql
rsa_encrypt ( 'a string', rsa_public(key) )
```

**Key**

- **KEY** should be a value returned by the RSA_PUBLIC function. LPARAM is an additional system-specific tag that can be applied to identify which system encrypted the message. Its default value is NULL.

- **<hash> ::= { MD5 | SHA1 | SHA256 | SHA512 }**
Default is SHA256.

Run your samples one by one from the RSA_PRIVATE function forward.

Example

```sql
select rdb$set_context('USER_SESSION', 'msg', rsa_encrypt('Some message'
    key rdb$get_context('USER_SESSION', 'public_key'))) from rdb$database;
```

**RSA_DECRYPT()**

Decrypts using the RSA private key and OAEP de-pads the resulting data.

**Syntax**

```sql
RSA_DECRYPT ( <string> KEY <private key> [LPARAM <string>] [HASH <hash>] )
```

KEY should be a value returned by the RSA_PRIVATE function. LPARAM is the same variable passed to RSA_ENCRYPT. If it does not match what was used during encryption, RSA_DECRYPT will not decrypt the packet.

```sql
<hash> ::= { MD5 | SHA1 | SHA256 | SHA512 }
```

Default is SHA256.

Run your samples one by one from the RSA_PRIVATE function forward.

Example

```sql
select rsa_decrypt(rdb$get_context('USER_SESSION', 'msg')
    key rdb$get_context('USER_SESSION', 'private_key')) from rdb$database;
```

**RSA_SIGN_HASH()**

Performs PSS encoding of the message digest to be signed and signs using the RSA private key.

**PSS encoding**

Probabilistic Signature Scheme (PSS) is a cryptographic signature scheme specifically developed to allow modern methods of security analysis to prove that its security directly relates to that of the RSA problem. There is no such proof for the traditional PKCS#1 v1.5 scheme.
Syntax

```
RSA_SIGN_HASH ( <message digest> KEY <private key> 
    [HASH <hash>] [SALT_LENGTH <smallint>] )
```

message digest is an already hashed message.

KEY should be a value returned by the RSA_PRIVATE function.

```
<hash> ::= { MD5 | SHA1 | SHA256 | SHA512 }
```

Default is SHA256. hash should match the hash algorithm used to generate the message hash value.

SALT_LENGTH indicates the length of the desired salt, and should typically be small. A good value is between 8 and 16.

- Run your samples one by one from the RSA_PRIVATE function forward.

Example

```
select rdb$set_context('USER_SESSION', 'msg', 
    rsa_sign_hash(crypt_hash('Test message' using sha256) 
    key rdb$get_context('USER_SESSION', 'private_key'))) from rdb$database;
```

**RSA_VERIFY_HASH()**

Performs PSS encoding of message digest to be signed and verifies its digital signature using the RSA public key.

Syntax

```
RSA_VERIFY_HASH ( 
    <message digest> SIGNATURE <string> 
    KEY <public key> [HASH <hash>] [SALT_LENGTH <smallint>] )
```

message digest is an already hashed message.

SIGNATURE should be a value returned by the RSA_SIGN_HASH function.

KEY should be a value returned by RSA_PUBLIC function.

```
<hash> ::= { MD5 | SHA1 | SHA256 | SHA512 }
```

Default is SHA256. The hash should match the hash algorithm used to generate the message digest value and the original signature.

SALT_LENGTH indicates the length of the desired salt, and should typically be small. A good value is
between 8 and 16.

Run your samples one by one from the RSA_PRIVATE function forward.

*Example*

```sql
select rsa_verify_hash(
    crypt_hash('Test message' using sha256)
    signature rdb$get_context('USER_SESSION', 'msg')
    key rdb$get_context('USER_SESSION', 'public_key'))
from rdb$database;
```

**Improvements to Security Features**

The following improvements were made to existing security features:

**User Managing Other Users**

Alex Peshkov

Tracker ticket **CORE-5770**

A user that was created with user account administration privileges in the security database (via the ... GRANT ADMIN ROLE clause) no longer has to hold the RDB$ADMIN role in the connected database and pass it explicitly in order to create, alter or drop other users.

This improvement is also backported to Firebird 3.0.5.
Chapter 8. Management Statements

Over the more recent releases of Firebird a new class of DSQL statement has emerged in Firebird's SQL lexicon, usually for administering aspects of the client/server environment. Typically, such statements commence with the verb SET, especially those introduced in Firebird 4.

Some statements of this class, introduced earlier, use the verb ALTER, although management statements should not be confused with DDL ALTER statements that modify database objects like tables, views, procedures, roles, et al.

Management statements can run anywhere DSQL can run but, typically, the developer will want to run a management statement in a database trigger. In past releases, management statements were treated in PSQL like DDL, precluding them from running directly inside a PSQL module. From Firebird 4 forward, a pre-determined set of them can be used directly in PSQL modules without the need to wrap them in an EXECUTE STATEMENT block. For more details of the current set, see Allow Management Statements in PSQL Blocks in the PSQL chapter.

Most of the management statements introduced in Firebird 4 affect the current connection (“session”) only, and do not require any authorization over and above the login privileges of a current user without elevated privileges.

Some management statements operate beyond the scope of the current session. Examples are the ALTER DATABASE … statements to control nBackup or the ALTER EXTERNAL CONNECTIONS POOL statements introduced in Firebird 4 to manage connection pooling. A new set of system privileges, analogous with SQL privileges granted for database objects, is provided for assignment to a role, to enable the required authority to run a specific management statement in this category. For details, refer to Enhanced System Privileges in the Security chapter.

Connections Pooling Management

A group of management statements for use with connections pooling.

Authorization

A role carrying the new system privilege MODIFY_EXT_CONN_POOL is required to run the statements.

ALTER EXTERNAL CONNECTIONS POOL

The new statement ALTER EXTERNAL CONNECTIONS POOL has been added to the repertoire for managing the external connections pool.

The syntax is:

ALTER EXTERNAL CONNECTIONS POOL { <parameter variants> }

When prepared it is described like a DDL statement but its effect is immediate—it is executed
immediately and completely, without waiting for transaction commit.

The statements can be issued from any connection, and changes are applied to the in-memory instance of the pool in the current Firebird process. If the process is a Classic one, a change submitted there does not affect other Classic processes.

Changes made with `ALTER EXTERNAL CONNECTIONS POOL` are not persistent: after a restart, Firebird will use the pool settings configured in `firebird.conf` by `ExtConnPoolSize` and `ExtConnPoolLifeTime`.

**Full Syntax**

Full syntax for the variants follows.

To set the maximum number of idle connections:

```
ALTER EXTERNAL CONNECTIONS POOL SET SIZE int_value
```

Valid values are from 0 to 1000. Setting it to zero disables the pool. The default value is set using the parameter `ExtConnPoolSize` in `firebird.conf`.

To set the lifetime of an idle connection:

```
ALTER EXTERNAL CONNECTIONS POOL SET LIFETIME int_value <time_part>
<time_part> ::= { SECOND | MINUTE | HOUR }
```

Valid values are from 1 SECOND to 24 HOUR. The default value (in seconds) is set using the parameter `ExtConnPoolLifetime` in `firebird.conf`.

To close all idle connections and instigate dissociation of all active connections so they are immediately closed when they become unused:

```
ALTER EXTERNAL CONNECTIONS POOL CLEAR ALL
```

To close expired idle connections:

```
ALTER EXTERNAL CONNECTIONS POOL CLEAR OLDEST
```

**ALTER SESSION RESET**

**Syntax**

```
ALTER SESSION RESET
```

This statement is used to reset the current user session to its initial state. It could be useful for re-
using the session by a client application (for example, by a client-side connection pool). In order to reuse a session, all its user context variables and contents of temporary tables should be cleared and all its session-level settings should be reset to their default values.

This statement is executed the following way:

- Error `isc_ses_reset_err` is raised if any transaction remains active in the current session, except of current transaction and two-phase-commit transactions in the prepared state.
- System variable `RESETTING` is set to TRUE.
- ON DISCONNECT database triggers are fired, if present and allowed for current connection.
- The current transaction (the one executing `ALTER SESSION RESET`), if present, is rolled back. A warning is reported if this transaction had modified some data in tables before resetting the session.
- `DECFLOAT` parameters (`TRAP` and `ROUND`) are reset to the initial values defined using DPB at connection time, or otherwise the system default
- Session and statement timeouts are reset to zero.
- Context variables defined for the 'USER_SESSION' namespace are removed.
- Global temporary tables defined as `ON COMMIT PRESERVE ROWS` are truncated (their contents is cleared).
- Current role is restored to the initial value defined using DPB at connection time, the security classes cache is cleared (if role was changed).
- The session time zone is reset to the initial value defined using DPB at connection time, or otherwise the system default.
- The bind configuration is reset to the initial value defined using DPB at connection time, or otherwise the database or system default.
- In general, configuration values should revert to values configured using DPB at connection time, or otherwise the database or system default.
- ON CONNECT database triggers are fired, if present and allowed for current connection.
- A new transaction is implicitly started with the same parameters as the transaction that was rolled back (if it was present).
- System variable `RESETTING` is set to FALSE.

Note, `CURRENT_USER` and `CURRENT_CONNECTION` will not be changed.

New system variable `RESETTING` is introduced to detect cases when a database trigger is fired due to session reset. It is available in triggers only and can be used in any place when a boolean predicate is allowed. Its value is TRUE if session reset is in progress and FALSE otherwise. `RESETTING` is a reserved word now.

**Errors handling**

Any error raised by ON DISCONNECT triggers aborts session reset and leaves the session state unchanged. Such errors are reported using primary error code `isc_session_reset_err` and error text...
"Cannot reset user session".

Any error raised after ON DISCONNECT triggers (including the ones raised by ON CONNECT triggers) aborts both session reset statement execution and connection itself. Such errors are reported using primary error code `isc_session_reset_failed` and error text "Reset of user session failed. Connection is shut down.". Subsequent operations on connection (except detach) will fail with `isc_att_shutdown error`.

**Time Zone Management**

Statement syntax has been added to support management of the time zone features for the current connection.

**SET TIME ZONE**

Changes the session time zone.

**Syntax**

```
SET TIME ZONE { time_zone_string | LOCAL }
```

**Examples**

```
set time zone '-02:00';
set time zone 'America/Sao_Paulo';
set time zone local;
```

**Timeout Management**

The timeout periods for session and statement timeouts can be managed at session level using the management statements `SET SESSION IDLE TIMEOUT` and `SET STATEMENT TIMEOUT`, respectively.

**Setting DECFLOAT Properties**

Syntax:

```
SET DECFLOAT <property-name> [TO] <value>
```

are available for controlling the properties of the DECFLOAT data type for the current session.

Possible properties and their values are the following:

- `SET DECFLOAT ROUND <mode>` controls the rounding mode used in operations with DECFLOAT values. Valid modes are:
CEILING  towards +infinity  
UP  away from 0  
HALF_UP  to nearest, if equidistant, then up  
HALF_EVEN  to nearest, if equidistant, ensure last digit in the result will be even  
HALF_DOWN  to nearest, if equidistant, then down  
DOWN  towards 0  
FLOOR  towards -infinity  
REROUND  up if digit to be rounded is 0 or 5, down in other cases

The default rounding mode is HALF-UP. The initial configuration may be specified via API by using DPB tag isc_dpb_decfloat_round followed by the string value.

- SET DECFLOAT TRAPS TO <comma-separated traps list which may be empty> controls which exceptional conditions cause a trap. Valid traps are:
  
  Division_by_zero  (set by default)  
  Inexact  —  
  Invalid_operation  (set by default)  
  Overflow  (set by default)  
  Underflow  —  

The initial configuration may be specified via API by using DPB tag isc_dpb_decfloat_traps followed by the string value.

**Setting Data Type Coercion Rules**

Syntax:

```
SET BIND OF { <type-from> | TIME ZONE } TO { <type-to> | LEGACY | NATIVE | EXTENDED }
```

This management statement makes it possible to substitute one data type with another one when performing the client-server interaction. In other words, type-from returned by the engine is represented as type-to in the client API.
Only fields returned by the database engine in regular messages are substituted according to these rules. Variables returned as an array slice are not affected by the SET BIND statement.

When an incomplete type definition is used (i.e. simply CHAR instead of CHAR(n)) in the FROM part, the coercion is performed for all CHAR columns. The special incomplete type TIME ZONE stands for all types WITH TIME ZONE (namely TIME and TIMESTAMP). When an incomplete type definition is used in the TO part, the engine defines missing details about that type automatically based on source column.

Changing the binding of any NUMERIC or DECIMAL data type does not affect the appropriate underlying integer type. In contrast, changing the binding of an integer data type also affects appropriate NUMERICs/DECIMALs.

The special format LEGACY is used when a data type, missing in previous Firebird version, should be represented in a way, understandable by old client software (possibly with some data loss). The coercion rules applied in this case are shown in the table below.

Table 1. Native to LEGACY coercion rules

<table>
<thead>
<tr>
<th>Native data type</th>
<th>Legacy data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>CHAR(5)</td>
</tr>
<tr>
<td>DECFLOAT</td>
<td>DOUBLE PRECISION</td>
</tr>
<tr>
<td>INT128</td>
<td>BIGINT</td>
</tr>
<tr>
<td>TIME WITH TIME ZONE</td>
<td>TIME WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>TIMESTAMP WITH TIME ZONE</td>
<td>TIMESTAMP WITHOUT TIME ZONE</td>
</tr>
</tbody>
</table>

Using EXTENDED in the TO part causes the engine to coerce to an extended form of the FROM data type. Currently, this works only for TIME/TIMESTAMP WITH TIME ZONE, they are coerced to EXTENDED TIME/TIMESTAMP WITH TIME ZONE. The EXTENDED type contains both the time zone name, and the corresponding GMT offset, so it remains usable if the client application cannot process named time zones properly (e.g. due to the missing ICU library).

Setting a binding to NATIVE resets the existing coercion rule for this data type and returns it in the native format.

Examples:
SELECT CAST('123.45' AS DECFLOAT(16)) FROM RDB$DATABASE;    --native

CAST
=======================
123.45

SET BIND OF DECFLOAT TO DOUBLE PRECISION;
SELECT CAST('123.45' AS DECFLOAT(16)) FROM RDB$DATABASE;    --double

CAST
=======================
123.4500000000000

SET BIND OF DECFLOAT(34) TO CHAR;
SELECT CAST('123.45' AS DECFLOAT(16)) FROM RDB$DATABASE;    --still double

CAST
=======================
123.4500000000000

SELECT CAST('123.45' AS DECFLOAT(34)) FROM RDB$DATABASE;    --text

CAST
=======================
123.45

In the case of missing ICU on the client side:

SELECT CURRENT_TIMESTAMP FROM RDB$DATABASE;

CURRENT_TIMESTAMP
=================================================================
2020-02-21 16:26:48.0230 GMT*

SET BIND OF TIME ZONE TO EXTENDED;
SELECT CURRENT_TIMESTAMP FROM RDB$DATABASE;

CURRENT_TIMESTAMP
=================================================================
2020-02-21 19:26:55.6820 +03:00

Extended Length for Object Names

Adriano dos Santos Fernandes

Tracker ticket CORE-749

The maximum length of object names from this version forward is 63 characters, up from the previous maximum of 31 bytes.

Multi-byte identifiers can also be long now. For example, the previous limit allowed only 15 Cyrillic characters; now, they could be up to 63.

Double quotes around a column name are not counted.

Restricting the Length

If, for some reason, you need to restrict the maximum size of object names, either globally or for individual databases, two new configuration parameters are available in firebird.conf and/or databases.conf: see Parameters to Restrict Length of Object Identifiers in the Configuration chapter for further details.

New Data Types

New data types implemented in Firebird 4.0:

Data Type INT128

Alex Peshkov

Tracker ticket CORE-6342
For details, see Increased Precision for Exact Numeric Types later in this chapter.

**Data Types TIME WITH TIME ZONE and TIMESTAMP WITH TIME ZONE**

Adriano dos Santos Fernandes

Tracker tickets CORE-694

For details, see Data Type Extensions for Time Zone Support later in this chapter.

**Data Type DECFLOAT**

Alex Peshkov

Tracker ticket CORE-5525

DECFLOAT is an SQL:2016 standard-compliant numeric type that stores floating-point numbers precisely (decimal floating-point type), unlike FLOAT or DOUBLE PRECISION that provide a binary approximation of the purported precision. Firebird 4 accords with the IEEE 754-1985 standard types Decimal64 and Decimal128 by providing both 16-digit and 34-digit precision for this type.

All intermediate calculations are performed with 34-digit values.

16-digit and 34-digit

The “16” and “34” refer to the maximum precision in Base-10 digits. See https://en.wikipedia.org/wiki/IEEE_754#Basic_and_interchange_formats for a comprehensive table.

**Syntax Rules**

```
DECFL0AT(16)
DECFL0AT(34)
DECFL0AT
```

The default precision is 34 digits, i.e., if DECFLOAT is declared with no parameter, it will be defined as DECFLOAT(34). Storage complies with IEEE 754, storing data as 64 and 128 bits, respectively.

**Examples**

```
DECLARE VARIABLE VAR1 DECFLOAT(34);
--
CREATE TABLE TABLE1 (FIELD1 DECFLOAT(16));
```

The precision of the DECFLOAT column or domain is stored in the system table RDB$FIELDS, in RDB$FIELD_PRECISION.
Aspects of DECFLOAT Usage

Length of Literals

The length of DECFLOAT literals cannot exceed 1024 characters. Scientific notation is required for longer values. For example, \(0.0\times10^{20}\) zeroes\(11\) cannot be used as a literal, the equivalent in scientific notation, \(1.1\times10^{-22}\) is valid. Similarly, \(10\times10^{22}\) zeroes\(0\) can be presented as \(1.0\times10^{24}\).

Use with Standard Functions

A number of standard scalar functions can be used with expressions and values of the DECFLOAT type. They are:

\[
\begin{array}{cccccc}
\text{ABS} & \text{CEILING} & \text{EXP} & \text{FLOOR} & \text{LN} \\
\text{LOG} & \text{LOG10} & \text{POWER} & \text{SIGN} & \text{SQRT}
\end{array}
\]

The aggregate functions SUM, AVG, MAX and MIN work with DECFLOAT data, as do all of the statistics aggregates (including but not limited to STDDEV or CORR).

Special Functions for DECFLOAT

Firebird supports four functions, designed to support DECFLOAT data specifically:

\text{COMPARE\_DECFLOAT} \\
\begin{array}{c}
\text{compares two DECFLOAT values to be equal, different or unordered}
\end{array}

\text{NORMALIZE\_DECFLOAT} \\
\begin{array}{c}
takes a single DECFLOAT argument and returns it in its simplest form
\end{array}

\text{QUANTIZE} \\
\begin{array}{c}
takes two DECFLOAT arguments and returns the first argument scaled using the second value as a pattern
\end{array}

\text{TOTALORDER} \\
\begin{array}{c}
performs an exact comparison on two DECFLOAT values
\end{array}

Detailed descriptions are in the DML chapter, in the topic Special Functions for DECFLOAT.

Session Control Operator SET DECFLOAT

Firebird supports the session control operator SET DECFLOAT that allows to change the DECFLOAT data type properties. For details, see Setting DECFLOAT Properties in the Management Statements chapter.

DDL Enhancements

Enhancements have been added to the SQL data definition language lexicon in Firebird 4 include a new, high-precision floating-point data type as well as other extensions.

New and extended DDL statements supporting the new security features are described in the
Security chapter.

**Increased Precision for Exact Numeric Types**

Alex Peshkov

Fixed types `NUMERIC` and `DECIMAL` can now be defined with up to 38 digits precision. Any value with precision higher than 18 digits will be stored as a 38-digit number. There's also an explicit `INT128` integer data type with 128-bit (up to 38 decimal digits) storage.

**Syntax rules**

```plaintext
INT128
NUMERIC [(P [, S] )]
DECIMAL [(P [, S] )]
```

where \( P \) is precision \((P \leq 38, \) previously limited to 18 digits\), and the optional \( S \) is scale, as previously, i.e., the number of digits after the decimal separator.

**Storage** for \( P \geq 19 \) is a 128-bit signed integer.

**Examples**

1. Declare a variable of 25 digits to behave like an integer:

   ```sql
   DECLARE VARIABLE VAR1 DECIMAL(25);
   ```

2. Define a column to accommodate up to 38 digits, with 19 decimal places:

   ```sql
   CREATE TABLE TABLE1 (FIELD1 NUMERIC(38, 19));
   ```

3. Define a procedure with input parameter defined as 128-bit integer:

   ```sql
   CREATE PROCEDURE PROC1 (PAR1 INT128) AS BEGIN END;
   ```

Numerics with precision less than 19 digits use `SMALLINT`, `INTEGER`, `BIGINT` or `DOUBLE PRECISION` as the base datatype, depending on the number of digits and SQL dialect. When precision is between 19 and 38 digits a 128-bit integer is used for internal storage, and the actual precision is always extended to the full 38 digits.

For complex calculations, those digits are cast internally to `DECFLOAT(34)`. The result of various mathematical operations, such as `LOG()`, `EXP()` and so on, and aggregate functions using a high precision numeric argument, will be `DECFLOAT(34)`.
**Standard Compliance for Data Type FLOAT**

Mark Rotteveel

FLOAT data type was enhanced to support precision in binary digits as defined in the SQL:2016 specification. The approximate numeric types supported by Firebird are a 32-bit single precision and a 64-bit double precision binary floating-point type. These types are available with the following SQL standard type names:

- **REAL** : 32-bit single precision (synonym for FLOAT)
- **FLOAT** : 32-bit single precision
- **FLOAT(P)** where P is the precision of the significand in binary digits
  - 1 \(\leq P \leq 24\) : 32-bit single precision (synonym for FLOAT)
  - 25 \(\leq P \leq 53\) : 64-bit double precision (synonym for DOUBLE PRECISION)
- **DOUBLE PRECISION** : 64-bit double precision

In addition the following non-standard type names are supported:

- **LONG FLOAT** : 64-bit double precision (synonym for DOUBLE PRECISION)
- **LONG FLOAT(P)** where P is the precision of the significand in binary digits (1 \(\leq P \leq 53\) : synonym for DOUBLE PRECISION)

These non-standard type names are deprecated and they may be removed in a future version.

**Compatibility Notes**

1. REAL has been available as a synonym for FLOAT since Firebird 1.0 and even earlier, but was never documented.
2. Firebird 3.0 and earlier supported FLOAT(P) where P was the approximate precision in decimal digits, with 0 \(\leq P \leq 7\) mapped to 32-bit single precision and \(P > 7\) mapped to 64-bit double precision. This syntax was never documented.
3. For P in FLOAT(P), the values 1 \(\leq P \leq 24\) are all treated as \(P = 24\), values 25 \(\leq P \leq 53\) are all handled as \(P = 53\).
4. Firebird 3.0 and earlier supported LONG FLOAT(P) where P was the approximate precision in decimal digits, where any value for P mapped to 64-bit double precision. This type name and syntax were never documented.
5. For P in LONG FLOAT(P), the values 1 \(\leq P \leq 53\) are all handled as \(P = 53\).

**Data Type Extensions for Time Zone Support**

Adriano dos Santos Fernandes

The syntax for declaring the data types **TIMESTAMP** and **TIME** has been extended to include arguments defining whether the column, domain, parameter or variable should be defined with or without time zone adjustments, i.e.,
For a summary of the effects of time zone support on existing data and application code, refer to Changes in DDL and DML Due to Timezone Support in the Compatibility chapter.

**Storage**

Data of types TIME/TIMESTAMP WITH TIME ZONE are stored respectively with the same storage as TIME/TIMESTAMP WITHOUT TIME ZONE plus two extra bytes for the time zone identifier or displacement.

- The time/timestamp parts, translated from the informed time zone, are stored in UTC.
- Time zone identifiers (from regions) are put directly in the time_zone bytes. They start from 65535, for the GMT code, decreasing as new time zones are added.

The time zone literals, together with their time zone identifiers, can be obtained from the RDB$TIME_ZONES system table.

- Time zone displacements (+/- HH:MM) are encoded with $(\text{sign} \times (\text{HH} \times 60 + \text{MM})) + 1439$.

  For example, a 00:00 displacement is encoded as $(1 \times (0 \times 60 + 0)) + 1439 = 1439$ and -02:00 as $(-1 \times (2 \times 60 + 0)) + 1439 = 1319$.

The default for both TIME and TIMESTAMP is WITHOUT TIME ZONE.

See also Management Statements Pertaining to Time Zone Support in the Management Statements chapter.

**Aliases for Binary String Types**

Dimitry Sibiryakov

Tracker ticket CORE-5064

Data types named BINARY(n), VARBINARY(n) and BINARY VARYING(n) have been added to the lexicon as optional aliases for defining string columns in CHARACTER SET OCTETS.

BINARY(n) is an alias for CHAR(n) CHARACTER SET OCTETS, while VARBINARY(n) and BINARY VARYING(n) are aliases for VARCHAR(n) CHARACTER SET OCTETS and for each other.

**Extensions to the IDENTITY Type**

Adriano dos Santos Fernandes

An IDENTITY column is one that is formally associated with an internal sequence generator and has its value set automatically when omitted from an INSERT statement.
The IDENTITY sub-type was introduced in Firebird 3 and has undergone a number of extensions in version 4, including implementation of DROP IDENTITY, the GENERATED ALWAYS and OVERRIDE directives, and the INCREMENT BY option.

### Extended Syntax for Managing IDENTITY Columns

```plaintext
<column definition> ::=  
  name <type> GENERATED { ALWAYS | BY DEFAULT } AS IDENTITY [ ( <identity column option>... ) ] <constraints>

<identity column option> ::=  
  START WITH value | INCREMENT [ BY ] value

<alter column definition> ::=  
  name <set identity column generation clause> [ <alter identity column option>... ] | 
  name <alter identity column option>... | 
  name DROP IDENTITY

<set identity column generation clause> ::=  
  SET GENERATED { ALWAYS | BY DEFAULT }

<alter identity column option> ::=  
  RESTART [ WITH value ] | SET INCREMENT [ BY ] value
```

### Rules and Characteristics

- The type of an identity column must be an exact number type with zero scale, comprising SMALLINT, INTEGER, BIGINT, NUMERIC\((p,0)\) and DECIMAL\((p,0)\) with \(1 \leq p \leq 18\).
- Identity columns cannot have a DEFAULT value or be defined as COMPUTED BY <expr>
- A regular column cannot be altered to be an identity column
- Identity columns cannot be defined or made non-nullable
- The engine does not enforce uniqueness automatically. A unique constraint or index of the required kind must be defined explicitly.
- An INCREMENT value cannot be zero

### The Firebird 4 Extensions to IDENTITY

The Firebird 3 implementation was minimal, effectively formalizing the traditional way of implementing generated keys in Firebird, without many options. Firebird 4 puts some meat on those bones.

#### The GENERATED ALWAYS and BY DEFAULT Directives

Tracker ticket **CORE-5463**

The earlier implementation behaved like the traditional Firebird setup for generating integer keys automatically when the column was omitted from the insert operation's column list. If the column was not listed, the IDENTITY generator would supply the value.
A `GENERATED BY` clause is mandatory. The `GENERATED BY DEFAULT` directive, present in the Firebird 3 syntax, implemented this behaviour formally without the alternative `GENERATED ALWAYS` option:

```sql
create table objects (
    id integer generated BY DEFAULT as identity primary key,
    name varchar(15)
);

insert into objects (name) values ('Table');
insert into objects (name) values ('Book');
insert into objects (id, name) values (10, 'Computer');

select * from objects order by id;
commit;
```

<table>
<thead>
<tr>
<th>ID</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Table</td>
</tr>
<tr>
<td>2</td>
<td>Book</td>
</tr>
<tr>
<td>10</td>
<td>Computer</td>
</tr>
</tbody>
</table>

The `GENERATED ALWAYS` directive introduces alternative behaviour that enforces the use of the identity generator, whether or not the user supplies a value.

**Overriding the defined behaviour**

For one-off cases this enforcement can be overridden in DML by including an `OVERRIDING SYSTEM VALUE` clause.

On the other hand, for one-off cases where you want to override the defined action for a column defined with the `GENERATED BY DEFAULT` directive to behave as though it were defined as `GENERATED ALWAYS` and ignore any DML-supplied value, the clause `OVERRIDING USER VALUE` is available.

For more details, see [OVERRIDING Clause for IDENTITY Columns](#) in the [Data Manipulation Language](#) chapter.

**Changing the Defined Behaviour**

The `ALTER COLUMN` clause of `ALTER TABLE` now has syntax for changing the default `GENERATED` behaviour from `BY DEFAULT` to `ALWAYS`, or vice versa:

```sql
alter table objects
    alter id
    SET GENERATED ALWAYS;
```
DROP IDENTITY Clause

Tracker ticket CORE-5431

For a situation where you want to drop the IDENTITY property from a column but retain the data, the DROP IDENTITY clause is available to the ALTER TABLE statement:

```sql
alter table objects
    alter id
    DROP IDENTITY;
```

INCREMENT BY Option for IDENTITY Columns

Tracker ticket CORE-5430

By default, identity columns start at 1 and increment by 1. The INCREMENT BY option can now be used to set the increment for some positive or negative step, i.e., 1 or more or -1 or less:

```sql
create table objects (  
id integer generated BY DEFAULT as  
    identity (START WITH 10000 INCREMENT BY 10)  
    primary key,  
    name varchar(15)  
);  
```

Changing the Increment (Step) Value

For changing the step value of the sequence produced by an IDENTITY generator, the SET INCREMENT clause is available in the ALTER TABLE statement syntax:

```sql
alter table objects  
    alter id SET INCREMENT BY 5;
```

1. Changing the step value does not affect existing data.
2. It is not necessary to specify SET INCREMENT BY 1 for a new column, nor for one that has not been altered previously, as the default step is 1.

Implementation

Two columns have been added to RDB$RELATION_FIELDS: RDB$GENERATOR_NAME and RDB$IDENTITY_TYPE. RDB$GENERATOR_NAME stores the automatically created generator for the column.

In RDB$GENERATORS, the value of RDB$SYSTEM_FLAG of that generator will be 6. RDB$IDENTITY_TYPE stores the value 0 for GENERATED ALWAYS, 1 for GENERATED BY DEFAULT, and NULL for non-identity columns.
Excess parameters in EXECUTE STATEMENT

Vlad Khorsun

Input parameters of the EXECUTE STATEMENT command may be prefixed by the EXCESS keyword. If EXCESS is specified, then the given parameter may be omitted from the query text.

Example

```sql
CREATE PROCEDURE P_EXCESS (A_ID INT, A_TRAN INT = NULL, A_CONN INT = NULL)
    RETURNS (ID INT, TRAN INT, CONN INT)
AS
DECLARE S VARCHAR(255);
DECLARE W VARCHAR(255) = '';
BEGIN
    S = 'SELECT * FROM TTT WHERE ID = :ID';

    IF (A_TRAN IS NOT NULL)
        THEN W = W || ' AND TRAN = :a';

    IF (A_CONN IS NOT NULL)
        THEN W = W || ' AND CONN = :b';

    IF (W <> '')
        THEN S = S || W;

    -- could raise error if TRAN or CONN is null
    -- FOR EXECUTE STATEMENT (:S) (a := :A_TRAN, b := A_CONN, id := A_ID)

    -- OK in all cases
    FOR EXECUTE STATEMENT (:S) (EXCESS a := :A_TRAN, EXCESS b := A_CONN, id := A_ID)
        INTO :ID, :TRAN, :CONN
        DO SUSPEND;
END
```

Replication Management

Dmitry Yemanov

Once replication is set up in the replication.conf configuration file, it can be enabled/disabled at runtime using the special extension to the ALTER DATABASE statement. Also, the replication set (i.e. tables to be replicated) can be customized using the extensions to the ALTER DATABASE and CREATE/ALTER TABLE statements.

Extended Syntax for Replication Management
ALTER DATABASE ... [<database replication management>]

CREATE TABLE tablename ... [<replication state>]
ALTER TABLE tablename ... [<replication state>]

<database replication management> ::= <replication state> |
  INCLUDE <replication set> TO PUBLICATION |
  EXCLUDE <replication set> FROM PUBLICATION

<replication state> ::= ENABLE PUBLICATION |
  DISABLE PUBLICATION

<replication set> ::= ALL | TABLE tablename [, tablename ...]

Comments

• All replication management commands are DDL statements and thus effectively executed at the transaction commit time.

• ALTER DATABASE ENABLE PUBLICATION allows replication to begin (or continue) with the next transaction started after this transaction commits.

• ALTER DATABASE DISABLE PUBLICATION disables replication immediately after commit.

• If INCLUDE ALL TO PUBLICATION clause is used, then all tables created afterwards will also be replicated, unless overridden explicitly in the CREATE TABLE statement.

• If EXCLUDE ALL FROM PUBLICATION clause is used, then all tables created afterwards will not be replicated, unless overridden explicitly in the CREATE TABLE statement.
Chapter 10. Data Manipulation Language (DML)

In this chapter are the additions and improvements that have been added to the SQL data manipulation language subset in Firebird 4.0.

Quick Links

- Lateral Derived Tables
- DEFAULT Context Value for Inserting and Updating
- OVERRIDING Clause for IDENTITY Columns
- Frames for Window Functions
- Named Windows
- More Window Functions
- FILTER Clause for Aggregate Functions
- Optional AUTOCOMMIT for SET TRANSACTION
- Sharing Transaction Snapshots
- Expressions and Built-in Functions
- UDF Changes
- Improve Error Message for an Invalid Write Operation
- Improved Failure Messages for Expression Indexes
- RETURNING * Now Supported

Lateral Derived Tables

Dmitry Yemanov

Tracker ticket CORE-3435

A derived table defined with the LATERAL keyword is called a lateral derived table. If a derived table is defined as lateral, then it is allowed to refer to other tables in the same FROM clause, but only those declared before it in the FROM clause.

The feature is defined in (SQL:2011): 7.6 <table reference> (Feature T491).
Examples

```sql
select dt.population, dt.city_name, c.country_name
from (select distinct country_name from cities) AS c,
    LATERAL (select first 1 city_name, population
            from cities
            where cities.country_name = c.country_name
            order by population desc) AS dt;

--
select salespeople.name,
    max_sale.amount,
    customer_of_max_sale.customer_name
from salespeople,
    LATERAL ( select max(amount) as amount from all_sales
                where all_sales.salesperson_id = salespeople.id
            ) as max_sale,
    LATERAL ( select customer_name from all_sales
                where all_sales.salesperson_id = salespeople.id
                and all_sales.amount = max_sale.amount
            ) as customer_of_max_sale;
```

**DEFAULT Context Value for Inserting and Updating**

Adriano dos Santos Fernandes

Tracker ticket **CORE-5449**

Support has been implemented to enable the declared default value for a column or domain to be included directly in INSERT, UPDATE, MERGE and UPDATE OR INSERT statements by use of the keyword `DEFAULT` in the column’s position. If `DEFAULT` appears in the position of a column that has no default value defined, the engine will attempt to write `NULL` to that column.

The feature is defined in (SQL:2011): 6.5 <contextually typed value specification>.

**Simple Examples**

```sql
insert into sometable (id, column1)
values (DEFAULT, 'name')

--
update sometable
  set column1 = 'a', column2 = default
```
If id is an identity column, the identity value will be generated, even if there is an UPDATE … SET command associated with the column.

If DEFAULT is specified on a computed column, the parser will allow it but it will have no effect.

In columns populated by triggers in the traditional way, the value from DEFAULT enters the NEW context variable of any BEFORE INSERT or BEFORE UPDATE trigger.

**DEFAULT vs DEFAULT VALUES**

Since version 2.1, Firebird has supported the DEFAULT VALUES clause. The two clauses are not the same. The DEFAULT clause applies to an individual column in the VALUES list, while DEFAULT VALUES applies to the row to be inserted as a whole. A statement like INSERT INTO sometable DEFAULT VALUES is equivalent to INSERT INTO sometable VALUES (DEFAULT, …) with as many DEFAULT in the VALUES list as there are columns in sometable.

**OVERRIDING Clause for IDENTITY Columns**

Adriano dos Santos Fernandes

Tracker ticket CORE-5463

Identity columns defined with the BY DEFAULT attribute can be overridden in statements that insert rows (INSERT, UPDATE OR INSERT, MERGE … WHEN NOT MATCHED) just by specifying the value in the values list. For identity columns defined with the GENERATE ALWAYS attribute, that kind of override is not allowed.

Making the value passed in the INSERT statement for an ALWAYS column acceptable to the engine requires use of the OVERRIDING clause with the SYSTEM VALUE sub-clause, as illustrated below:

```sql
insert into objects (id, name)
    OVERRIDING SYSTEM VALUE values (11, 'Laptop');
```

OVERRIDING supports another sub-clause, USER VALUE, for use with BY DEFAULT columns to direct the engine to ignore the value passed in INSERT and use the sequence defined for the identity column:

```sql
insert into objects (id, name)
    OVERRIDING USER VALUE values (12, 'Laptop');  -- 12 is not used
```

**Extension of SQL Windowing Features**

Adriano dos Santos Fernandes

The OVER clause for Window functions in Firebird now supports not just the sub-clauses PARTITION and ORDER subclauses but also frames and windows with names that can be re-used in the same
query.

The pattern for Firebird 4 windowing syntax is as follows:

**Syntax Pattern**

```plaintext
<window function> ::=  
    <window function name>([, <expr> ...]) 
    OVER {<window specification> | existing_window_name} 

<window specification> ::=  
    ([existing_window_name] [<window partition>] [<window order>] [<window frame>]) 

>window partition> ::=  
    PARTITION BY <expr> [, <expr> ...] 

>window order> ::=  
    ORDER BY <expr> [<direction>] [nulls placement] 
    [, <expr> [<direction>] [nulls placement]>] ... 

>window frame> ::=  
    {RANGE | ROWS} <window frame extent> 

>window frame extent> ::=  
    {<window frame start> | <window frame between>} 

>window frame start> ::=  
    {UNBOUNDED PRECEDING | <expr> PRECEDING | CURRENT ROW} 

/window frame between> ::=  
    BETWEEN <window frame bound 1> AND <window frame bound 2> 

/window frame bound 1> ::=  
    {UNBOUNDED PRECEDING | <expr> PRECEDING | <expr> FOLLOWING | CURRENT ROW} 

/window frame bound 2> ::=  
    {UNBOUNDED FOLLOWING | <expr> PRECEDING | <expr> FOLLOWING | CURRENT ROW} 

/direction> ::=  
    {ASC | DESC} 

/nulls placement> ::=  
    NULLS {FIRST | LAST} 

/query spec> ::=  
    SELECT 
    [limit clause] 
    [distinct clause] 
    <select list> 
    <from clause> 
    [where clause] 
```
Frames for Window Functions

Tracker ticket **CORE-3647**

A *frame* can be specified, within which certain window functions are to work.

The following extract from the syntax pattern above explains the elements that affect frames:

**Syntax Elements for Frames**

```
<window frame> ::= 
    {RANGE | ROWS} <window frame extent>

<window frame extent> ::= 
    {<window frame start> | <window frame between>}

<window frame start> ::= 
    {UNBOUNDED PRECEDING | <expr> PRECEDING | CURRENT ROW}

<window frame between> ::= 
    BETWEEN <window frame bound 1> AND <window frame bound 2>

<window frame bound 1> ::= 
    {UNBOUNDED PRECEDING | <expr> PRECEDING | <expr> FOLLOWING | CURRENT ROW}

<window frame bound 2> ::= 
    {UNBOUNDED FOLLOWING | <expr> PRECEDING | <expr> FOLLOWING | CURRENT ROW}
```

The frame comprises three pieces: unit, start bound and end bound. The unit can be RANGE or ROWS and defines how the bounds will work. The bounds are:

- `<expr> PRECEDING`
- `<expr> FOLLOWING`
- `CURRENT ROW`

- With RANGE, the ORDER BY should specify only one expression, and that expression should be of a numeric, date, time or timestamp type. For `<expr> PRECEDING` and `<expr> FOLLOWING` bounds, `<expr>` is subtracted from the order expression in the case of PRECEDING and added to it in the
case of FOLLOWING. For CURRENT ROW, the order expression is used as-is.

All rows inside the partition that are between the bounds are considered part of the resulting window frame.

• With ROWS, order expressions are not limited by number or type. For this unit, <expr> PRECEDING, <expr> FOLLOWING and CURRENT ROW relate to the row position under the partition, and not to the values of the ordering keys.

UNBOUNDED PRECEDING and UNBOUNDED FOLLOWING work identically with RANGE and ROWS. UNBOUNDED PRECEDING looks for the first row and UNBOUNDED FOLLOWING the last one, always inside the partition.

The frame syntax with <window frame start> specifies the start frame, with the end frame being CURRENT ROW.

Some window functions discard frames:

• ROW_NUMBER, LAG and LEAD always work as ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
• DENSE_RANK, RANK, PERCENT_RANK and CUME_DIST always work as RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW.
• FIRST_VALUE, LAST_VALUE and NTH_VALUE respect frames, but the RANGE unit behaviour is identical to ROWS.

Navigational Functions with Frames

Navigational functions, implemented in Firebird 3, get the simple (non-aggregated) value of an expression from another row that is within the same partition. They can operate on frames. These are the syntax patterns:

```
<navigational window function> ::= 
FIRST_VALUE(<expr>) | 
LAST_VALUE(<expr>) | 
NTH_VALUE(<expr>, <offset>) [FROM FIRST | FROM LAST] | 
LAG(<expr> [ [, <offset> [, <default> ] ] ] ) | 
LEAD(<expr> [ [, <offset> [, <default> ] ] ] )
```

The default frame is RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW which might produce strange results when a frame with these properties is operated on by FIRST_VALUE, NTH_VALUE or, particularly, LAST_VALUE.

Example Using Frames

When the ORDER BY window clause is used, but a frame clause is omitted, the default frame just described causes the query below to produce weird behaviour for the sum_salary column. It sums from the partition start to the current key, instead of summing the whole partition.
```sql
select
    id,
    salary,
    sum(salary) over (order by salary) sum_salary
from employee
order by salary;
```

Result:

<table>
<thead>
<tr>
<th>id</th>
<th>salary</th>
<th align="right">sum_salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>8.00</td>
<td align="right">8.00</td>
</tr>
<tr>
<td>4</td>
<td>9.00</td>
<td align="right">17.00</td>
</tr>
<tr>
<td>1</td>
<td>10.00</td>
<td align="right">37.00</td>
</tr>
<tr>
<td>5</td>
<td>10.00</td>
<td align="right">37.00</td>
</tr>
<tr>
<td>2</td>
<td>12.00</td>
<td align="right">49.00</td>
</tr>
</tbody>
</table>

A frame can be set explicitly to sum the whole partition, as follows:

```sql
select
    id,
    salary,
    sum(salary) over (order by salary
                          ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
                      ) sum_salary
from employee
order by salary;
```

Result:

<table>
<thead>
<tr>
<th>id</th>
<th>salary</th>
<th align="right">sum_salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>8.00</td>
<td align="right">49.00</td>
</tr>
<tr>
<td>4</td>
<td>9.00</td>
<td align="right">49.00</td>
</tr>
<tr>
<td>1</td>
<td>10.00</td>
<td align="right">49.00</td>
</tr>
<tr>
<td>5</td>
<td>10.00</td>
<td align="right">49.00</td>
</tr>
<tr>
<td>2</td>
<td>12.00</td>
<td align="right">49.00</td>
</tr>
</tbody>
</table>

This query “fixes” the weird nature of the default frame clause, producing a result similar to a simple `OVER ()` clause without `ORDER BY`.

We can use a range frame to compute the count of employees with salaries between (an employee’s salary - 1) and (his salary + 1) with this query:
```sql
select
    id,
    salary,
    count(*) over (  
        order by salary  
        RANGE BETWEEN 1 PRECEDING AND 1 FOLLOWING  
    ) range_count
from employee
order by salary;
```

Result:

<table>
<thead>
<tr>
<th>id</th>
<th align="right">salary</th>
<th align="right">range_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td align="right">8.00</td>
<td align="right">2</td>
</tr>
<tr>
<td>4</td>
<td align="right">9.00</td>
<td align="right">4</td>
</tr>
<tr>
<td>1</td>
<td align="right">10.00</td>
<td align="right">3</td>
</tr>
<tr>
<td>5</td>
<td align="right">10.00</td>
<td align="right">3</td>
</tr>
<tr>
<td>2</td>
<td align="right">12.00</td>
<td align="right">1</td>
</tr>
</tbody>
</table>

**Named Windows**

Tracker ticket [CORE-5346](#)

In a query with the WINDOW clause, a window can be explicitly named to avoid repetitive or confusing expressions.

A named window can be used

a. in the OVER element to reference a window definition, e.g. `OVER <window-name>`

b. as a base window of another named or inline (OVER) window, if it is not a window with a frame (ROWS or RANGE clauses).

A window with a base window cannot have PARTITION BY, nor override the ordering (ORDER BY sequence) of a base window.

In a query with multiple SELECT and WINDOW clauses (for example, with subqueries), the scope of the window name is confined to its query context. That means a window name from an inner context cannot be used in an outer context, nor vice versa. However, the same window name definition can be used independently in different contexts.
Example Using Named Windows

```sql
select
  id,
  department,
  salary,
  count(*) over w1,
  first_value(salary) over w2,
  last_value(salary) over w2
from employee
window w1 as (partition by department),
  w2 as (w1 order by salary)
order by department, salary;
```

More Window Functions

Adriano dos Santos Fernandes; Hajime Nakagami

Tracker ticket CORE-1688

More SQL:2003 window functions — the ranking functions PERCENT_RANK, CUME_DIST and NTILE.

Ranking Functions

```sql
<ranking window function> ::= 
  DENSE_RANK() |
  RANK() |
  PERCENT_RANK() |
  CUME_DIST() |
  NTILE(<expr>) |
  ROW_NUMBER()
```

Ranking functions compute the ordinal rank of a row within the window partition. The basic functions in this category, present since Firebird 3, are DENSE_RANK, RANK and ROW_NUMBER. These function enable creation of various types of incremental counters to generate sets in ways that are analogous with operations such as SUM(1) OVER (ORDER BY SALARY).

The new functions implemented in Firebird 4 are:

- **PERCENT_RANK** is a ratio of RANK to group count.
- **CUME_DIST** is the cumulative distribution of a value in a group.
- **NTILE** takes an argument and distributes the rows into the specified number of groups. The argument is restricted to integral positive literal, variable (:var) and DSQL parameter (?).

The following example illustrates the behaviour of ranking functions. SUM is included for comparison.
Simple Example

```sql
select
  id,
  salary,
  dense_rank() over (order by salary),
  rank() over (order by salary),
  percent_rank() over (order by salary),
  cume_dist() over (order by salary),
  ntile(3) over (order by salary),
  row_number() over (order by salary),
  sum(1) over (order by salary)
from employee
order by salary;
```

The result set looks something like the following, although trailing zeroes have been truncated here in order to fit the lines to the document page:

<table>
<thead>
<tr>
<th>id</th>
<th>salary</th>
<th>dense_rank</th>
<th>rank</th>
<th>percent_rank</th>
<th>cume_dist</th>
<th>ntile</th>
<th>row_number</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>8.00</td>
<td>1</td>
<td>1</td>
<td>0.000000</td>
<td>0.2000000</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>9.00</td>
<td>2</td>
<td>2</td>
<td>0.250000</td>
<td>0.4000000</td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>10.00</td>
<td>3</td>
<td>3</td>
<td>0.500000</td>
<td>0.8000000</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>10.00</td>
<td>3</td>
<td>3</td>
<td>0.500000</td>
<td>0.8000000</td>
<td>2</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>12.00</td>
<td>4</td>
<td>5</td>
<td>1.000000</td>
<td>1.0000000</td>
<td>3</td>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>

FILTER Clause for Aggregate Functions

Adriano dos Santos Fernandes

Tracker ticket **CORE-5768**

The **FILTER** clause extends aggregate functions (sum, avg, count, etc.) with an additional **WHERE** clause. The set returned is the aggregate of the rows that satisfy the conditions of both the main **WHERE** clause and those inside the **FILTER** clause(s).

It can be thought of as a shortcut for situations where one would use an aggregate function with some condition (decode, case, iif) to ignore some of the values that would be considered by the aggregation.

The clause can be used with any aggregate functions in aggregate or windowed (OVER) statements, but not with window-only functions like DENSE_RANK.

**Example**

Suppose you have a query where you want to count the number of status = 'A' and the number of status = 'E' as different columns. The old way to do it would be:
The FILTER clause lets you express those conditions more explicitly:

```
select count(*) filter (where status = 'A') status_a,
     count(*) filter (where status = 'E') status_e
from data;
```

You can use more than one FILTER modifier in an aggregate query. You could, for example, use 12 filters on totals aggregating sales for a year to produce monthly figures for a pivot set.

**Syntax for FILTER Clauses**

```
aggregate_function [FILTER (WHERE <condition>)] [OVER (<window>)]
```

**Optional AUTOCOMMIT for SET TRANSACTION**

Dmitry Yemanov

Tracker ticket CORE-5119

Autocommit mode is now supported in the SET TRANSACTION statement syntax.

*Example*

```
SET TRANSACTION SNAPSHOT NO WAIT AUTO COMMIT;
```

**Sharing Transaction Snapshots**

Adriano dos Santos Fernandes

Tracker ticket CORE-6018

With this feature it's possible to create parallel processes (using different attachments) reading consistent data from a database. For example, a backup process may create multiple threads reading data from the database in parallel. Or a web service may dispatch distributed sub-services doing some processing in parallel.

For this purpose, the SET TRANSACTION statement is extended with the SNAPSHOT [ AT NUMBER snapshot_number ] option. Alternatively, this feature can also be used via API, new Transaction Parameter Buffer item isc_tpb_at_snapshot_number <snapshot number length> snapshot_number is
added for this purpose.

The `snapshot_number` from an active transaction can be obtained with `RDB$GET_CONTEXT('SYSTEM', 'SNAPSHOT_NUMBER')` in SQL or using the transaction information API call with `fb_info_tra_snapshot_number` information tag. Note that the `snapshot_number` passed to the new transaction must be a snapshot of a currently active transaction.

Example

```
SET TRANSACTION SNAPSHOT AT NUMBER 12345;
```
LOCALTIMESTAMP Expression

Returns the current timestamp as a TIMESTAMP WITHOUT TIME ZONE, in the session time zone.

Example

```
select localtimestamp from rdb$database;
```

Two New Date/Time Functions

Adriano dos Santos Fernandes

FIRST_DAY

Returns a date or timestamp (as appropriate) with the first day of the year, month or week of a given date or timestamp value.

Syntax

```
FIRST_DAY( OF { YEAR | MONTH | WEEK } FROM <date_or_timestamp> )
```

a. The first day of the week is considered as Sunday, following the same rules as for EXTRACT with WEEKDAY
b. When a timestamp is passed the return value preserves the time part

Examples

```
select first_day(of month from current_date) from rdb$database;
select first_day(of year from current_timestamp) from rdb$database;
select first_day(of week from date '2017-11-01') from rdb$database;
```

LAST_DAY

Returns a date or timestamp (as appropriate) with the last day of the year, month or week of a given date or timestamp value.

Syntax

```
LAST_DAY( OF { YEAR | MONTH | WEEK } FROM <date_or_timestamp> )
```

a. The last day of the week is considered as Saturday, following the same rules as for EXTRACT with WEEKDAY
b. When a timestamp is passed the return value preserves the time part

Examples

```
select last_day(of month from current_date) from rdb$database;
select last_day(of year from current_timestamp) from rdb$database;
select last_day(of week from date '2017-11-01') from rdb$database;
```
Security Functions

Two new built-in functions were added to support the new security features. They are not described here — the descriptions are located in the Security chapter. They are:

- **RDB$SYSTEM_PRIVILEGE**
- **RDB$ROLE_IN_USE**

A number of cryptographic functions were also added. See Built-in Cryptographic Functions in the Security chapter for syntax and usage details.

Special Functions for DECFLOAT

Firebird supports four functions, designed to support DECFLOAT data specifically:

**COMPARE_DECFLT**

- compares two DECFLOAT values to be equal, different or unordered. Returns a SMALLINT value, one of:
  - 0  Values are equal
  - 1  First value is less than second
  - 2  First value is greater than second
  - 3  Values are unordered, i.e., one or both is NaN / sNaN

Unlike the comparison operators (‘<’, ‘=’, ‘>’, etc.) comparison is exact: COMPARE_DECFLT(2.17, 2.170) returns 2, not 0.

**NORMALIZE_DECFLT**

- takes a single DECFLOAT argument and returns it in its simplest form. That means that for any non-zero value, trailing zeros are removed with appropriate correction of the exponent.

For example, NORMALIZE_DECFLT(12.00) returns 12 and NORMALIZE_DECFLT(120) returns 1.2E+2.

**QUANTIZE**

- takes two DECFLOAT arguments. The returned value is the first argument scaled using the second value as a pattern.

For example, QUANTIZE(1234, 9.999) returns 1234.000.

There are almost no restrictions on the pattern. However, in almost all usages, sNaN will produce an exception, NULL will make the function return NULL, and so on.
If scaling like the example produces a result that would exceed the precision, the error “Decimal float invalid operation” is returned.

**TOTALORDER**

**TOTALORDER** compares two **DECFLOAT** values including any special value. The comparison is exact. Returns a **SMALLINT** value, one of:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>First value is less than second</td>
</tr>
<tr>
<td>0</td>
<td>Values are equal</td>
</tr>
<tr>
<td>1</td>
<td>First value is greater than second</td>
</tr>
</tbody>
</table>

For **TOTALORDER** comparisons, **DECFLOAT** values are ordered as follows:

- NaN < -sNaN < -INF < -0.1 < -0.10 < -0 < 0 < 0.10 < 0.1 < INF < sNaN < NaN

**Function RDB$GET_TRANSACTION_CN: Supporting Snapshots Based on Commit Order**

Vlad Khorsun

See Tracker ticket **CORE-5921**. For the background, see Commit Order for Capturing the Database Snapshot in the Engine chapter.

Returns the commit number (“CN”) of the supplied transaction. Result type is **BIGINT**.

**Syntax**

```
RDB$GET_TRANSACTION_CN( <transaction number> )
```

If the return value is greater than 1, it is the actual CN of the transaction if it was committed after the database was started.
The function can also return one of the following results, indicating the commit status of the transaction:

-2  Transaction is dead (rolled back)
-1  Transaction is in limbo
0   Transaction is still active
1   Transaction committed before the database started or less than the Oldest Interesting Transaction for the database
NULL Transaction number supplied is NULL or greater than Next Transaction for the database

Note about the numerics

Internally, the engine uses unsigned 8-byte integers for commit numbers and unsigned 6-byte integers for transaction numbers. Thus, although the SQL language has no unsigned integers and RDB$GET_TRANSACTION_CN returns a signed BIGINT, a negative commit number will only be returned for the special values returned for uncommitted transactions.

Examples

```
select rdb$get_transaction_cn(current_transaction) from rdb$database;
select rdb$get_transaction_cn(123) from rdb$database;
```

Function MAKE_DBKEY

Vlad Khorsun

Creates a DBKEY value using relation name or ID, record number, and (optionally) logical number of data page and pointer page. Result type is BINARY(8).

Syntax

```
MAKE_DBKEY( relation, recnum [, dpnum [, ppnum]] )
```

Notes

1. If `relation` is a string expression or literal, then it is treated as a relation name, and the engine searches for the corresponding relation ID. The search is case-sensitive. In the case of string literal, relation ID is evaluated at query preparation time. In the case of expression, relation ID is evaluated at execution time. If the relation could not be found, then error `isc_relnotdef` is raised.

2. If `relation` is a numeric expression or literal, then it is treated as a relation ID and used “as is”, without verification against existing relations. If the argument value is negative or greater than
the maximum allowed relation ID (65535 currently), then NULL is returned.

3. Argument *recnum* represents an absolute record number in the relation (if the next arguments *dpnum* and *ppnum* are missing), or a record number relative to the first record, specified by the next arguments.

4. Argument *dpnum* is a logical number of data page in the relation (if the next argument *ppnum* is missing), or number of data page relative to the first data page addressed by the given *ppnum*.

5. Argument *ppnum* is a logical number of pointer page in the relation.

6. All numbers are zero-based. Maximum allowed value for *dpnum* and *ppnum* is $2^{32}$ (4294967296).
   If *dpnum* is specified, then *recnum* could be negative. If *dpnum* is missing and *recnum* is negative, then NULL is returned. If *ppnum* is specified, then *dpnum* could be negative. If *ppnum* is missing and *dpnum* is negative, then NULL is returned.

7. If any of specified arguments has NULL value, the result is also NULL.

8. Argument 

Examples

```sql
-- (1) Select record using relation name
-- (note: relation name is upppercased)
select * from rdb$relations where rdb$db_key = make_dbkey('RDB$RELATIONS', 0)

-- (2) Select record using relation ID
select * from rdb$relations where rdb$db_key = make_dbkey(6, 0)

-- (3) Select all records physically residing on the first data page
select * from rdb$relations
where rdb$db_key >= make_dbkey(6, 0, 0)
and rdb$db_key < make_dbkey(6, 0, 1)

-- (4) Select all records physically residing on the first data page
-- of 6th pointer page
select * from SOMETABLE
where rdb$db_key >= make_dbkey('SOMETABLE', 0, 0, 5)
and rdb$db_key < make_dbkey('SOMETABLE', 0, 1, 5)
```

**BASE64_ENCODE() and BASE64_DECODE()**

Alex Peshkov

These two functions are for encoding and decoding input data between string and BASE64 representation. They operate with character strings and BLOBs. Considered useful when working with binary objects, for example with keys.
Syntax

BASE64_ENCODE( binary_data )
BASE64_DECODE( base64_data )

Example

select base64_encode(public_key) from clients;

**HEX_ENCODE() and HEX_DECODE()**

Alex Peshkov

These two functions are for encoding and decoding input data between string and hexadecimal representation. They operate with character strings and BLOBs.

Syntax

HEX_ENCODE( binary_data )
HEX_DECODEx ( hex_data )

Example

select hex_encode(binary_string) from clients;

**CRYPT_HASH()**

Alex Peshkov

Accepts an argument than can be a field, variable or expression of any type recognized by DSQ/L/PSQL and returns a cryptographic hash calculated from the input argument using the specified algorithm.

Syntax

CRYPT_HASH( <any value> USING <algorithm> )

<algorithm> ::= { MD5 | SHA1 | SHA256 | SHA512 }

Example

select crypt_hash(job_title using sha256) from job;
This function returns a VARBINARY string with the length depending on the specified algorithm.

- MD5 and SHA1 algorithms are not recommended due to known severe issues, these algorithms are provided for backward compatibility ONLY.

Changes to Built-in Functions and Expressions

Functions changed or extended in this release:

Changes Arising from Timezone Support

**EXTRACT Expressions**

Two new arguments have been added to the `EXTRACT` expression:

- `TIMEZONE_HOUR` extracts the time zone hours displacement
- `TIMEZONE_MINUTE` extracts the time zone minutes displacement

**Example**

```sql
select extract(timezone_hour from current_time) from rdb$database;
select extract(timezone_minute from current_timestamp) from rdb$database;
```

Changes in `CURRENT_TIME` and `CURRENT_TIMESTAMP`

In version 4.0, `CURRENT_TIME` and `CURRENT_TIMESTAMP` are changed: they now return `TIME WITH TIME ZONE` and `TIMESTAMP WITH TIME ZONE`, with the time zone set by the session time zone. In previous versions, `CURRENT_TIME` and `CURRENT_TIMESTAMP` returned the respective types according to the system clock, i.e. without any time zone.

To ease the transition, `LOCALTIME` and `LOCALTIMESTAMP` were added to versions 3.0.4 and 2.5.9, allowing developers to adjust application code without any functional changes, before migrating to Firebird 4.

See also Changes in DDL and DML Due to Timezone Support in the Compatibility chapter.

**HASH()**

Adriano dos Santos Fernandes

Tracker ticket CORE-4436

Returns a generic hash for the input argument using the specified algorithm.
Syntax

```
HASH( <any value> [ USING <algorithm> ] )
```

```
<algorithm> ::= { CRC32 }
```

The syntax with the optional USING clause is introduced in FB 4.0 and returns an integer of appropriate size. CRC32 algorithm implemented by Firebird uses polynomial 0x04C11DB7.

The syntax without the USING clause is still supported. It uses the 64-bit variation of the non-cryptographic PJW hash function (also known as ELF64):

```
https://en.wikipedia.org/wiki/PJW_hash_function
```

which is very fast and can be used for general purposes (hash tables, etc), but its collision quality is sub-optimal. Other hash functions (specified explicitly in the USING clause) should be used for more reliable hashing.

Examples

```
select hash(x using crc32) from y;
--
select hash(x) from y; -- not recommended
```

**SUBSTRING()**

A SUBSTRING start position smaller than 1 is now allowed. It has some properties that need to be taken into consideration for predicting the end of the string value returned.

Examples

```
select substring('abcdef' from 0) from rdb$database
-- Expected result: 'abcdef'

select substring('abcdef' from 0 for 2) from rdb$database
-- Expected result: 'a' (and NOT 'ab', because there is "nothing" at position 0)

select substring('abcdef' from -5 for 2) from rdb$database
-- Expected result: ''
```

Those last two examples might not be what you expect. The for length is considered from the specified from start position, not the start of the string, so the string returned could be shorter than the specified length, or even empty.

**UDF Changes**

Many of the UDFs in previous versions became built-in functions. The UDF feature itself is heavily
deprecated in Firebird 4 — see External Functions (UDFs) Feature Deprecated in the Engine chapter. Most of the remaining UDFs in the ib_udf and fbudf libraries now have analogues, either as UDRs in the new library udf_compat or as precompiled PSQL functions.

A script in the /misc/upgrade/v4.0/ sub-directory of your installation provides an easy way to upgrade existing UDF declarations to the safe form that is available for each respective UDF. For details and instructions, see Deprecation of External Functions (UDFs) in the Compatibility chapter.

**New UDR GetExactTimestampUTC**

The new UDR GetExactTimestampUTC, in the udf_compat library, takes no input argument and returns the TIMESTAMP WITH TIME ZONE value at the moment the function is called.

The older function, GetExactTimestamp has been refactored as a stored function, returning, as before, the TIMESTAMP WITHOUT TIME ZONE value at the moment the function is called.

**Miscellaneous DML Improvements**

Improvements to behaviour and performance in DML include:

**Improve Error Message for an Invalid Write Operation**

Adriano dos Santos Fernandes

See Tracker ticket CORE-5874.

When a read-only column is incorrectly targeted in an UPDATE … SET xxx operation, the error message now provides the name of the affected column.

**Improved Failure Messages for Expression Indexes**

Adriano dos Santos Fernandes

Tracker ticket CORE-5606

If computation of an expression index fails, the exception message will now include the name of the index.

**RETURNING * Now Supported**

Adriano dos Santos Fernandes

Tracker ticket CORE-3808

The engine now supports RETURNING * syntax, and variants, to return a complete set of field values after committing a row that has been inserted, updated or deleted. The syntax and semantics of RETURNING * are similar to SELECT *.
Examples

INSERT INTO T1 (F1, F2) VALUES (:F1, :F2) RETURNING *

DELETE FROM T1 WHERE F1 = 1 RETURNING *

UPDATE T1 SET F2 = F2 * 10 RETURNING OLD.*, NEW.*
Recursion is now supported in sub-routines. A few improvements have been implemented to help in logging exceptions from the various error contexts supported in PSQL.

**Recursion for subroutines**

Adriano dos Santos Fernandes

Tracker ticket [CORE-5380](#)

Starting in FB 4, subroutines may be recursive or call other subroutines.

*A couple of recursive sub-functions in EXECUTE BLOCK*

```sql
execute block returns (i integer, o integer)
as
    -- Recursive function without forward declaration.
    declare function fibonacci(n integer) returns integer
    as
    begin
        if (n = 0 or n = 1) then
            return n;
        else
            return fibonacci(n - 1) + fibonacci(n - 2);
        end
    begin
        i = 0;
        while (i < 10)
            do
                begin
                    o = fibonacci(i);
                    suspend;
                    i = i + 1;
                end
        end
```
-- With forward declaration and parameter with default values
execute block returns (o integer) as
   -- Forward declaration of P1.
   declare procedure p1(i integer = 1) returns (o integer);

   -- Forward declaration of P2.
   declare procedure p2(i integer) returns (o integer);

   -- Implementation of P1 should not re-declare parameter default value.
   declare procedure p1(i integer) returns (o integer) as begin
      execute procedure p2(i) returning_values o;
   end

   declare procedure p2(i integer) returns (o integer) as begin
      o = i;
      begin
         execute procedure p1 returning_values o;
         suspend;
      end
   end

A Helper for Logging Context Errors

A new system function enables the module to pass explicit context information from the error block to a logging routine.

System Function RDB$ERROR()

Dmitry Yemanov

Tracker tickets CORE-2040 and CORE-1132

The function RDB$ERROR() takes a PSQL error context as input and returns the specific context of the active exception. Its scope is confined to the context of the exception-handling block in PSQL. Outside the exception handling block, RDB$ERROR always returns NULL.

The type of the return value depends on the context.

Syntax

RDB$ERROR ( <context> )
<context> ::= { GDSCODE | SQLCODE | SQLSTATE | EXCEPTION | MESSAGE }
### Contexts

<table>
<thead>
<tr>
<th>Context</th>
<th>Type/Character Set</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GDSCODE</td>
<td>INTEGER</td>
<td>Context variable: refer to documentation</td>
</tr>
<tr>
<td>SQLCODE</td>
<td>INTEGER</td>
<td>Context variable: refer to documentation</td>
</tr>
<tr>
<td>SQLSTATE</td>
<td>CHAR(5) ASCII</td>
<td>Context variable: refer to documentation</td>
</tr>
<tr>
<td>EXCEPTION</td>
<td>VARCHAR(63) UTF8</td>
<td>Returns name of the active user-defined exception or NULL if the active exception is a system one</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>VARCHAR(1024) UTF8</td>
<td>Returns interpreted text for the active exception</td>
</tr>
</tbody>
</table>

For descriptions of the context variables GDSCODE, SQLCODE and SQLSTATE, refer to the Context Variables topic in the Firebird 2.5 Language Reference.

### Example of RDB$ERROR

```sql
BEGIN
...
WHEN ANY DO
    EXECUTE PROCEDURE P_LOG_EXCEPTION(RDB$ERROR(MESSAGE));
END
```

### Allow Management Statements in PSQL Blocks

Adriano dos Santos Fernandes

See Tracker ticket CORE-5887.

In prior Firebird versions, management statements were not allowed inside PSQL blocks. They were allowed only as top-level SQL statements, or as the top-level statement of an EXECUTE STATEMENT embedded in a PSQL block.

Now they can be used directly in PSQL blocks (triggers, procedures, EXECUTE BLOCK), which is especially helpful for applications that need some management statements to be issued at the start of a session, specifically in ON CONNECT triggers.

The management statements permitted for this usage are:
ALTER SESSION RESET
SET BIND
SET DECFLOAT ROUND
SET DECFLOAT TRAPS TO
SET ROLE
SET SESSION IDLE TIMEOUT
SET STATEMENT TIMEOUT
SET TIME ZONE
SET TRUSTED ROLE

Example

create or alter trigger on_connect on connect
as
begin
    set bind of decfloat to double precision;
    set time zone 'America/Sao_Paulo';
end
Chapter 12. Monitoring & Command-line Utilities

Improvements and additions to the Firebird utilities continue.

**Monitoring**

Additions to `MON$ATTACHMENTS` and `MON$STATEMENTS` to report on timeouts and wire status. Refer to *Timeouts at Two levels* in the chapter *Changes in the Firebird Engine* for details.

New columns in the tables:

<table>
<thead>
<tr>
<th>Table</th>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>In MON$DATABASE:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>MON$CRYPT_STATE</td>
<td>Current state of database encryption (not encrypted = 0, encrypted = 1, decryption in progress = 2, encryption in progress = 3)</td>
<td></td>
</tr>
<tr>
<td>MON$GUID</td>
<td>Database GUID (persistent until restore / fixup)</td>
<td></td>
</tr>
<tr>
<td>MON$FILE_ID</td>
<td>Unique ID of the database file at the filesystem level</td>
<td></td>
</tr>
<tr>
<td>MON$NEXT_ATTACHMENT</td>
<td>Current value of the next attachment ID counter</td>
<td></td>
</tr>
<tr>
<td>MON$NEXT_STATEMENT</td>
<td>Current value of the next statement ID counter</td>
<td></td>
</tr>
<tr>
<td>MON$REPLICA_MODE</td>
<td>Database replica mode (not a replica = 0, read-only replica = 1, read-write replica = 2)</td>
<td></td>
</tr>
<tr>
<td><strong>In MON$ATTACHMENTS:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>MON$IDLE_TIMEOUT</td>
<td>Connection level idle timeout</td>
<td></td>
</tr>
<tr>
<td>MON$IDLE_TIMER</td>
<td>Idle timer expiration time</td>
<td></td>
</tr>
<tr>
<td>MON$STATEMENT_TIMEOUT</td>
<td>Connection level statement timeout</td>
<td></td>

**nbackup**

**UUID-based Backup and In-Place Merge**

Roman Simakov; Vlad Khorsun

Tracker ticket **CORE-2216**

The *nBackup* utility in Firebird 4 can perform a physical backup that uses the GUID (UUID) of the most recent backup of a read-only standby database to establish the backup target file. Increments from the *source database* can be applied continuously to the standby database, eliminating the need to keep and apply all increments since the last full backup.

The new style of “warm” backup and merge to a standby database can be run without affecting an existing multilevel backup scheme on the live database.

**Making Backups**

The syntax pattern for this form of backup with *nBackup* is as follows:

```
nbackup -B[ACKUP] <level> | <GUID> <source database> [<backup file>]
```

**Merging-in-Place from the Backup**

The syntax pattern for an in-place “restore” to merge the incremental backup file with the standby database is:

```
nbackup -I[NPLACE] -R[ESTORE] <standby database> <backup file>
```

“Restore” here means merging the increment from the backup file with the standby database.

**Switch names may change before the final release.**

**Example of an On-line Backup and Restore**

a. Use *gstat* to get the UUID of the standby database:
gstat -h <standby database>
...
Variable header data:
Database backup GUID: {8C519E3A-FC64-4414-72A8-1B456C91D82C}

b. Use the backup UUID to produce an incremental backup:

nbackup -B {8C519E3A-FC64-4414-72A8-1B456C91D82C} <source database> <backup file>

c. Apply increment to the standby database:

nbackup -I -R <standby database> <backup file>

### Restore and Fixup for Replica Database

New (optional) command-line option -sequence (can be abbreviated to -seq) has been added for -restore and -fixup commands. It preserves the existing GUID and replication sequence of the original database (they are reset otherwise). This option should be used when creating a replica using nbackup tool, so that the asynchronous replication could automagically be continued from the point when a physical backup was performed on the primary side.

The syntax pattern is:

nbackup -R[ESTORE] <database file> <backup file> -SEQ[EUENCE]
nbackup -F[IXUP] <database file> -SEQ[EUENCE]

### isql

#### Support for Statement Timeouts

A new command has been introduced in isql to enable an execution timeout in milliseconds to be set for the next statement. The syntax is:

```
SET LOCAL_TIMEOUT <int>
```

After statement execution, the timer is automatically reset to zero.

#### Better transaction control

A new command has been introduced in isql to remember and reuse the last entered transaction parameters. The syntax is:
SET KEEP_TRAN_PARAMS [{ ON | OFF}]

When set to ON, *isql* keeps the complete SQL text of the following successful SET TRANSACTION statement and new transactions are started using the same SQL text (instead of the default CONCURRENCY WAIT mode). When set to OFF, *isql* starts new transactions as usual. Name KEEP_TRAN can be used as a shorthand for KEEP_TRAN_PARAMS.

**Examples**

```sql
-- check current value
SQL> SET;
...
Keep transaction params: OFF

-- toggle value
SQL> SET KEEP_TRAN;
SQL> SET;
...
Keep transaction params: ON
SET TRANSACTION

SQL> commit;

-- start new transaction, check KEEP_TRAN value and actual transaction's parameters
SQL> SET TRANSACTION READ COMMITTED WAIT;
SQL> SET;
...
Keep transaction params: ON
SET TRANSACTION READ COMMITTED WAIT
SQL> SELECT RDB$GET_CONTEXT('SYSTEM', 'ISOLATION_LEVEL') FROM RDB$DATABASE;

RDB$GET_CONTEXT

=================================================================================================
READ COMMITTED

SQL> commit;

-- start new transaction, ensure is have parameters as KEEP_TRAN value
SQL> SELECT RDB$GET_CONTEXT('SYSTEM', 'ISOLATION_LEVEL') FROM RDB$DATABASE;

RDB$GET_CONTEXT

=================================================================================================
READ COMMITTED

-- disable KEEP_TRAN, current transaction is not changed
SQL> SET KEEP_TRAN OFF;
SQL> SELECT RDB$GET_CONTEXT('SYSTEM', 'ISOLATION_LEVEL') FROM RDB$DATABASE;
```
RDB$GET_CONTEXT

============================================================================================================================
READ COMMITTED

SQL> commit;

-- start new transaction, ensure is has default parameters (SNAPSHOT)
SQL> SELECT RDB$GET_CONTEXT('SYSTEM', 'ISOLATION_LEVEL') FROM RDB$DATABASE;

RDB$GET_CONTEXT

============================================================================================================================
SNAPSHOT

SQL> SET;
...
Keep transaction params: OFF

---

gbak

Backup and Restore with Encryption

Alex Peshkov

Tracker ticket CORE-5808

With an encrypted database, sooner or later it will need to be backed up and restored. It is not unreasonable to want the database backup to be encrypted as well. If the encryption key is delivered to the plug-in by some means that does not require input from the client application, it is not a big problem. However, if the server expects the key to be delivered from the client side, that could become a problem.

The introduction of keys to gbak in Firebird 4 provides a solution.

Prerequisites

A keyholder plug-in is required. This plug-in is able to load keys from some external source, such as a configuration file, and deliver them using the call

ICryptKeyCallback* IKeyHolderPlugin::chainHandle(IStatus* status)

That key holder and the dbcrypt plug-ins that work with it should be installed on the workstation that will be used to perform backups.

New Switches for Encrypted Backups & Restores

With the prerequisites in place, the following new switches are available for use. They are case-
Table 2. Switches for Encrypted Backups/Restores

<table>
<thead>
<tr>
<th>Switch</th>
<th>What it Does</th>
</tr>
</thead>
<tbody>
<tr>
<td>-KEYHOLDER</td>
<td>This is the main switch necessary for <em>gbak</em> to access an encrypted database.</td>
</tr>
<tr>
<td>-KEYNAME</td>
<td>Available to name the key explicitly, in place of the default key specified in the original database (when backing up) or in the backup file (when restoring).</td>
</tr>
<tr>
<td>-CRYPT</td>
<td>Available to name the plug-in to use to encrypt the backup file or restored database in place of the default plug-in. It can also be used in combination with the -KEYNAME switch to encrypt the backup of a non-encrypted database or to encrypt a database restored from a non-encrypted backup. See example below.</td>
</tr>
<tr>
<td>-ZIP</td>
<td>Only for a backup, to compress the backup file before encrypting it. The switch is necessary because the usual approach of compressing the backup file with some favoured compression routine after <em>gbak</em>, perhaps using pipe, does not work with encrypted backups because they are not compressible. The -ZIP switch is unnecessary for a restore because the format is detected automatically.</td>
</tr>
</tbody>
</table>

Usage and Examples

To back up an encrypted database do something like this:

```bash
gbak -b -keyholder MyKeyHolderPlugin host:dbname backup_file_name
```

The backup file will be encrypted using the same crypt plug-in and key that are used for database encryption. This ensures that it will not be any easier to steal data from your backup file than from the database.

To restore a database that was previously backed up encrypted:

```bash
gbak -c -keyholder MyKeyHolderPlugin backup_file_name host:dbname
```

The restored database will be encrypted using the same plug-in and key as the backup file. Using the backup example above, of course this means the same plug-in and key as the original database.

The database is first encrypted right after creation and only after the encryption data are restored into the header. This is a bit faster than a “restore-then-encrypt” approach but, mainly, it is to avoid having non-encrypted data on the server during the restore process.

The next example will either:
• restore the database from a backup file made using non-default Crypt and Keyholder plug-ins, using the same key name as was used for the backup; OR
• restore a non-encrypted backup as an encrypted database

    gbak -c -keyholder MyKeyHolderPlugin -crypt MyDbCryptPlugin
        -keyname SomeKey non_encrypted_backup_file host:dbname

    The restored database will encrypted by MyDbCryptPlugin using SomeKey.

To make an encrypted backup of a non-encrypted database:

    gbak -b -keyholder MyKeyHolderPlugin -crypt MyDbCryptPlugin
        -keyname SomeKey host:dbname encrypted_backup_file

**Take note:**
Attempts to create a non-encrypted backup of an encrypted database or to restore an encrypted backup to a non-encrypted database will fail. Such operations are intentionally disallowed to avoid foolish operator errors that would expose critical data in non-encrypted form.

To create a compressed, encrypted backup:

    gbak -b -keyholder MyKeyHolderPlugin -zip host:dbname backup_file_name

    The backup file will be compressed before being encrypted using the same crypt plug-in and same key that are used for the database encryption. ZLib is used to compress the backup file content and the appropriate record is added to its header.

**Compressing Non-Encrypted Databases**
The -ZIP switch is also available for compressing a non-encrypted database. It is important to understand that the format of a backup file thus created is not the same as one created by compressing a backup file with a utility such as 7Zip. It can be decompressed only by a gbak restore.

**Enhanced Restore Performance**
Alex Peshkov
Tracker ticket CORE-5952
The new Batch API is used to enhance the performance of restoring from backup.

**Friendlier “-fix_fss_*” Messages**
Alex Peshkov
Tracker ticket CORE-5741

The messages in the verbose output from a restore using the “-fix_fss_*” switches now use the word “adjusting” instead of “fixing”.

The same change was backported to version 3.0.5.

**Ability to Backup/Restore Only Specified Tables**

Dimitry Sibiryakov

Tracker ticket CORE-5538

A new command-line switch has been added to *gbak*: `-INCLUDE(_DATA)`. Similarly to the existing `-SKIP(_DATA)` switch, it accepts one parameter which is a regular expression pattern used to match table names. If specified, it defines tables to be backed up or restored. The regular expression syntax used to match table names is the same as in *SIMILAR TO* Boolean expressions. Interaction between both switches is described in the following table.

*Table 3. Interaction between -INCLUDE(_DATA) and -SKIP(_DATA) switches*

<table>
<thead>
<tr>
<th>INCLUDE_DATA</th>
<th>NOT SET</th>
<th>MATCHED</th>
<th>NOT MATCHED</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT SET</td>
<td>included</td>

<tr>
<td>NOT MATCHED</td>
<td>included</td>
<td>included</td>
<td>excluded</td>
</tr>
</tbody>
</table>

*gfix*

**Configuring and managing replication**

The *gfix* repertoire now includes the new `-replica` switch for configuring and managing Firebird replication. For more detail, see the topic [Creating a Replica Database](#).

It takes one of three arguments (case-insensitive):

**read_only**

Sets the database copy as a read-only replica, usually for a high-availability solution.

**read_write**

Sets the database copy as a read-write replica, e.g. for merging external changes into a database.

**none**

Converts the replica to a regular database, “switching off” replication to a read-write replica when conditions call for replication flow to be discontinued for some reason. Typically, it would be used to promote the replica to become the master database after a failure; or to make physical backup copies from the replica.
Chapter 13. Compatibility Issues

In this section are features and modifications that might affect the way you have installed and used Firebird in earlier releases.

SQL

Changes that may affect existing SQL code:

Deprecation of Legacy SQL Dialect 1

Starting with Firebird 4, Dialect 1 is declared deprecated. Its support will be removed in future Firebird versions, with Dialect 3 becoming the only dialect supported. Please consider migrating to Dialect 3 as soon as possible.

Read Consistency for READ COMMITTED transactions Used By Default

Firebird 4 not only introduces Read Consistency for Statements in Read-Committed Transactions, but also makes it a default mode for all READ COMMITTED transactions, regardless of their RECORD VERSION or NO RECORD VERSION properties. This is done to provide users with better behaviour — both compliant with the SQL specification and less conflict-prone. However, this new behaviour may also have unexpected side effects, please read the aforementioned chapter carefully. If specifics of the READ CONSISTENCY mode are undesirable for some reasons, the configuration setting ReadConsistency may be changed to allow the legacy behaviour. See more details about the ReadConsistency setting in the Configuration Additions and Changes chapter.

Deprecation of External Functions (UDFs)

Support for the external function (UDF) feature is deprecated in Firebird 4. Its immediate effect, out of the box, is that UDFs cannot be used with the default configuration, where the parameter UdfAccess in firebird.conf is set to None) and the UDF libraries ib_udf and fbudf are withdrawn from the distribution.

Most of the functions in those libraries were already deprecated in previous Firebird versions and replaced with built-in analogues. Safe replacements for a few of the remaining functions are now available, either in a new library of user-defined routines (UDRs) named [lib]udf_compat.[dll/so/dylib], or as scripted conversions to PSQL stored functions. They are listed below; those marked with asterisks (*) are the UDR conversions.

<table>
<thead>
<tr>
<th>UDF</th>
<th>UDR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDDAY()</td>
<td>*DOW()</td>
<td>ROUND()</td>
</tr>
<tr>
<td>ADDDAY2()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADDHOUR()</td>
<td>DPOWER()</td>
<td>RTRIM()</td>
</tr>
<tr>
<td>ADDMILLISECOND()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADDMINUTE()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADDMONTH()</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ADDSECOND()</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>*SDOW()</td>
<td></td>
</tr>
<tr>
<td></td>
<td>*GETEXACTTIMESTAMP</td>
<td>SNULLIF()</td>
</tr>
<tr>
<td></td>
<td>*GETEXACTTIMESTAMPPUTC</td>
<td></td>
</tr>
<tr>
<td></td>
<td>I64NULLIF()</td>
<td>SNVL()</td>
</tr>
<tr>
<td></td>
<td>I64NVL()</td>
<td>SRIGHT()</td>
</tr>
<tr>
<td></td>
<td>I64ROUND()</td>
<td>STRING2BLOB()</td>
</tr>
</tbody>
</table>
The Firebird 4 distribution contains a script to migrate all (or any) of those UDF declarations. You can edit and extract from it to suit, if you wish, but you must keep the respective re-declarations and conversions intact as scripted.

**The UDF Migration Script**

The SQL script that you can use to upgrade the declarations for the UDFs listed above to the analogue UDRs or stored functions is located beneath the Firebird root, in `misc/upgrade/v4.0/udf_replace.sql`.

**How to Work with the Script**

During the restore of your Firebird 3 backup, `gbak` will issue warnings about any UDFs that are affected, but the restore will proceed. It would be useful to output the `-verbose` reporting to a file if you want a list of the affected function declarations. You will note items like

```
gbak: WARNING:function UDF_FRAC is not defined
gbak: WARNING:    module name or entrypoint could not be found
```

It means you have a UDF that is declared in the database but whose library is missing — which, of course, we know is true.

**Running the Script**

From the command shell:

```
isql -user sysdba -pas masterkey -i udf_replace.sql {your-database}
```

**REMINDER**

This script will have no effect on declarations for UDFs from third-party libraries!

**What If You MUST Use a UDF?**

In the short term, if you absolutely cannot avoid retaining the use of a UDF, you must configure the `UdfAccess` parameter to `Restrict <path-list>`. The default `<path-list>` points to the UDF sub-directory beneath the Firebird root. The (uncommented!) line in `firebird.conf` should be:

```
UdfAccess = Restrict UDF
```
Chapter 13. Compatibility Issues

The libraries [lib]ib_udf.[dll/so/dylib] and [lib]fbudf.[dll/so/dylib] that were distributed with Firebird 3 were tested to work with Firebird 4. No tests were done for any third-party or custom UDF libraries but, considering that nothing changed in the way Firebird works with UDFs, other than the default value for UdfAccess, they should also work.

The recommended long-term solution for any UDFs which you absolutely must use is to replace them with UDRs or stored functions.

Changes in DDL and DML Due to Timezone Support

Timezone support introduces some changes in DDL and DML which could affect compatibility with existing databases and applications.

Changes to Data Types TIMESTAMP and TIME

The syntax for declaring the data types TIMESTAMP and TIME has been extended to include arguments defining whether the column, domain, parameter or variable should be defined with or without time zone adjustments, i.e.:

```
TIME [ { WITHOUT | WITH } TIME ZONE ]
TIMESTAMP [ { WITHOUT | WITH } TIME ZONE ]
```

The default in both cases is WITHOUT TIME ZONE. If you are shifting migrated databases and/or applications to use the zoned date/time features, it is advisable to run reality checks on any calculations, computed fields, domains, query sets ordered or grouped by dates or timestamps, etc.

For more details, see Data Type Extensions for Time Zone Support in the DDL chapter.

CURRENT_TIME and CURRENT_TIMESTAMP

In version 4.0, CURRENT_TIME and CURRENT_TIMESTAMP are changed: they now return TIME WITH TIME ZONE and TIMESTAMP WITH TIME ZONE, with the time zone set by the session time zone. In previous versions, CURRENT_TIME and CURRENT_TIMESTAMP returned the respective types according to the system clock, i.e. without any time zone.

The expressions LOCALTIMESTAMP and LOCALTIME now replace the former functionality of CURRENT_TIMESTAMP and CURRENT_TIME, respectively.

Firebird 3.0.4 LOCALTIME and LOCALTIMESTAMP

To ease the transition, LOCALTIME and LOCALTIMESTAMP were added to versions 3.0.4 and 2.5.9, allowing developers to adjust application and PSQL code without any functional changes, before migrating to Firebird 4.

Prefixed Implicit Date/Time Literals Now Rejected

The literal date/time syntax (DATE, TIME or TIMESTAMP prefixing the quoted value) used together with the implicit date/time literal expressions ('NOW', 'TODAY', etc.) was known to evaluate those
expressions in ways that would produce unexpected results, often undetected:

- In stored procedures and functions, evaluation would occur at compile time but not during the procedure or function call, storing the result in BLR and retrieving that stale value at runtime.
- In DSQL, this style of usage in DSQL causes the evaluation to occur at prepare time, not at each iteration of the statement as would be expected with correct usage of the implicit date/time literals. The time difference between statement preparation and execution may be too small to discover the issue, particularly with 'NOW', which is a timestamp. Users could have been misled thinking the expression was evaluated at each iteration of the statement at runtime, when in fact it happened at prepare time.

If something like `TIMESTAMP 'NOW'` has been used in DSQL queries in application code or in migrated PSQL, there will be a compatibility issue with Firebird 4.

The behaviour was considered undesirable—the Firebird 4.0 engine and above will now reject such expressions in both PSQL and DSQL.

Example of such usage that will now be rejected:

```sql
.. DECLARE VARIABLE moment TIMESTAMP;
  ..
  SELECT TIMESTAMP 'NOW' FROM RDB$DATABASE INTO :moment;
  /* here, the variable :moment will 'frozen' as the timestamp at the moment the procedure or function was last compiled */
  ..
```

`TIMESTAMP '<constant>'` is for explicit date/time literals, e.g. `DATE '2019-02-20'` is legal. The implicit date/time literals, such as 'NOW' or 'YESTERDAY' are for use in expressions. Enforcement of the appropriate usage means that attempting to combine both becomes explicitly invalid syntax.

Existing code where usage does not break the rule remains unaffected. Both 'NOW' and `CAST('NOW' AS TIMESTAMP)` continue to work as before, as well as code that correctly uses the date/time prefixes with explicit literals, like `DATE '2019-02-20'`.

### Starting Value of Sequences

Before Firebird 4.0 a sequence was created with its current value set to its starting value (or zero by default). So a sequence with starting value = 0 and increment = 1 starts at 1. While such a sequence has the same result in Firebird 4.0 (i.e. also starts at 1), the underlying implementation is different, thus making other cases different.

Now a sequence is created (or restarted) with its current value set to its starting value minus its increment. And the default starting value is changed to 1. Then a sequence with starting value = 100 and increment = 10 has its first NEXT VALUE equal to 100 now, while it was 110 before. Likewise, this sequence has its first GEN_ID(SEQ, 1) equal to 91 now, while it was 101 before.
INSERT ... RETURNING Now Requires a SELECT privilege

If some INSERT statement contains a RETURNING clause that refers columns of the underlying table, the appropriate SELECT privilege must be granted to the caller.

Utilities

Deprecation of QLI

Starting with Firebird 4, command-line utility QLI is declared deprecated. It will be removed in future Firebird versions.
Chapter 14. Bugs Fixed

Firebird 4.0 Release: Bug Fixes

The following bug-fixes since the Release Candidate 1 are noted:

Core Engine

(#6816) — Illegal output length in BASE64/HEX ENCODE/DECODE functions.

fixed by A. Peshkov

(#6812) — BASE64_ENCODE and HEX_ENCODE can exceed the maximum length for VARCHAR.

fixed by A. Peshkov

(#6805) — RDB$TYPES has incorrect entries for RDB$TYPE 28 and 29 in RDB$TYPE_NAME column.

fixed by A. Peshkov

(#6804) — Assertion in tomcrypt when the key length for RC4 is too small.

fixed by A. Peshkov

(#6800) — Client config setting DefaultTimeZone is not passed to server when isc_dpb_session_time_zone is not set.

fixed by A. dos Santos Fernandes

(#6797) — Functions DECRYPT and RSA_DECRYPT return VARCHAR CHARACTER SET NONE instead of VARBINARY (VARCHAR CHARACTER SET OCTETS).

fixed by A. Peshkov

(#6795) — Replication gets stuck due to "Blob xxx.xx is not found for table xxx" error.

fixed by D. Yemanov

(#6790) — MON$ATTACHMENTS.MON$TIMESTAMP is incorrect when DefaultTimeZone is configured with time
zone different from the server's default.

fixed by A. dos Santos Fernandes

(#6787) — MON$ATTACHMENTS.MON$TIMESTAMP should use its session original time zone.

fixed by A. dos Santos Fernandes

(#6785) — Problem when restoring the database on Firebird 4 RC1.

fixed by V. Khorsun

(#6782) — Cannot get "records fetched" for selectable procedures in trace.

fixed by V. Khorsun

(#6778) — Inconsistent cursor-driven deletion.

fixed by D. Yemanov

(#6768) — Cannot restore backup on a raw device (error during "open O_CREAT" operation for file "/dev/sda1").

fixed by A. Peshkov

(#6761) — Hash join cannot match records using some TIME_ZONEx/DECFLOAT keys.

fixed by D. Yemanov

(#6759) — Results of concatenation with blob has no info about collation of source columns (which are declared with such info).

fixed by V. Khorsun

(#6758) — COMPUTED BY column looses charset and collate of source field <F> when <F> is either of type BLOB or VARCHAR casted to BLOB.

fixed by V. Khorsun
Chapter 14. Bugs Fixed

(#6756) — Error "no current record for fetch operation" when sorting by an international string.
fixed by D. Yemanov

(#6750) — CAST of Infinity values to FLOAT doesn’t work.
fixed by A. Peshkov

(#6749) — Error "Invalid time zone (+08). Falling back to displacement" in firebird.log.
fixed by A. dos Santos Fernandes

(#6747) — Wrong message when connecting to tiny trash database file.
fixed by A. Peshkov

(#6746) — Regression: CREATE DATABASE fails with 'Token unknown' error when DB name is enclosed in double quotes and 'DEFAULT CHARACTER SET' is specified after DB name.
fixed by A. dos Santos Fernandes

(#6734) — Provide same results for date arithmetics when date is changed by values near +/- max(bigint).
fixed by A. Peshkov

(#6733) — Attempt to create database with page_size >= 65536 makes DB with actual page size = 4KB or 8KB, but not 32KB as it should.
fixed by A. Peshkov

(#6727) — Synchronous replication to localhost hangs on disconnect.
fixed by D. Yemanov

(#6724) — Inconsistent translation "string → timestamp → string → timestamp" in Dialect 1.
fixed by A. dos Santos Fernandes
(###6719) — User without ALTER ANY ROLE privilege can use COMMENT ON ROLE.

fixed by A. Peshkov

(###6717) — FETCH ABSOLUTE and RELATIVE beyond bounds of cursor should always position immediately before-first or after-last.

fixed by D. Yemanov

(###6716) — FETCH RELATIVE has an off by one error for the first row.

fixed by D. Yemanov

(###6710) — COMMENT ON USER can only apply comment on user defined by the default user manager plugin.

fixed by A. Peshkov

(###6700) — Wire compression causes sporadic "Error reading data from the connection" errors.

fixed by A. Peshkov

(###6698) — Comments before the first line of code are removed.

fixed by A. dos Santos Fernandes

(###3810) — Wrong or missing IS NULL optimization.

fixed by V. Khorsun

(###3106) — Many indexed reads in a compound index with NULLs.

fixed by V. Khorsun

(###2469) — Stored procedure recursively called by calculated field fails after reconnect.

fixed by V. Khorsun
Server Crashes/Hang-ups

(#6808) — Segfault in ENCRYPT/DECRYPT functions when their first argument is \textit{NULL}.

\textit{fixed by A. Peshkov}

(#6781) — Crashing (due to UDF exception) process hangs.

\textit{fixed by V. Khorsun}

(#6777) — AV when the engine shuts down and cancels an attachment waiting in the lock manager.

\textit{fixed by V. Khorsun}

(#6766) — Replication plugin can crash the engine by returning \textit{nullptr} from \textit{startTransaction()} method.

\textit{fixed by D. Yemanov}

(#6754) — Connect to database that contains broken pages can lead to a server crash.

\textit{fixed by A. Peshkov}

(#6753) — AV in the engine when \textit{StatementTimeout} is active for user statement and some internal DSQL statement was executed as part of overall execution process.

\textit{fixed by V. Khorsun}

(#6752) — Segfaults in \textit{fbclient} when receiving invalid / unexpected data from the server.

\textit{fixed by A. Peshkov}

(#6751) — Various segfaults in \textit{fbclient}.

\textit{fixed by A. Peshkov}

(#6738) — Segfault when \textit{GFIX} requests for database page buffer more memory than available from OS.

\textit{fixed by A. Peshkov}
Chapter 14. Bugs Fixed

(#6731) — Segfault when shutting down database which got encrypted by another process.

fixed by A. Peshkov

(#6708) — Rare race condition in Plugin Manager could lead to the server crash.

fixed by V. Khorsun

(#6265) — Segfault when using expression index with complex expression.

fixed by V. Khorsun

(#5784) — When 32-bit and 64-bit Firebird 3 servers run on a single Windows machine concurrently, Firebird services freeze several minutes after first disconnect.

fixed by V. Khorsun

API/Remote Interface

(#6718) — Event delivery could be missed when local (XNET) protocol is used.

fixed by V. Khorsun

(#6679) — CLOOP envelopes are wrong regarding IStatus.

fixed by A. Peshkov

Build Issues

(#6780) — firebird.msg is missing in Firebird Android builds.

fixed by A. Peshkov

(#6745) — Protect included tomcrypt library from being overwritten by a system package.

fixed by A. Peshkov
Utilities

isql

(#6796) — Buffer overflow when padding line with national characters causes ISQL to crash.

fixed by A. dos Santos Fernandes

gbak

(#6709) — GBAK discards replica mode during backup/restore.

fixed by D. Yemanov

gstat

(#6729) — Regression: GSTAT with switch -t executed via services fails with "found unknown switch" error.

fixed by A. Peshkov

Firebird 4.0 Release Candidate 1: Bug Fixes

The following bug-fixes since the Beta 2 release are noted:

Core Engine

(CORE-6475) — Memory leak when running EXECUTE STATEMENT with named parameters.

fixed by V. Khorsun

(CORE-6472) — Wrong byte order for UUIDs reported by GSTAT and monitoring tables.

fixed by D. Sibiryakov

(CORE-6460) — Incorrect query result when using named window.

fixed by V. Khorsun

(CORE-6453) — EXECUTE STATEMENT fails on FB 4.x if containing time/timestamp with time zone parameters.
**CORE-6447** — Unexpectedly different text of message for parameterized expression starting from second run. Same fix was backported to Firebird 3.0.8.

fixed by V. Khorsun

**CORE-6441** — Srp plugin keeps connection after database has been removed for ~10 seconds. Same fix was backported to Firebird 3.0.8.

fixed by A. Peshkov

**CORE-6440** — Expression indexes containing `COALESCE` inside cannot be matched by the optimizer after migration from v2.5 to v3.0. Same fix was backported to Firebird 3.0.8.

fixed by D. Yemanov

**CORE-6437** — GFIX cannot set big value for page buffers. Same fix was backported to Firebird 3.0.8.

fixed by V. Khorsun

**CORE-6427** — Whitespace as date separator causes conversion error.

fixed by A. dos Santos Fernandes

**CORE-6421** — Parameter in offset expression in `LAG`, `LEAD`, `NTH_VALUE` window functions requires explicit cast to `BIGINT` or `INTEGER`.

fixed by A. dos Santos Fernandes

**CORE-6419** — Truncation of strings to put in MON$ tables do not work correctly.

fixed by A. dos Santos Fernandes

**CORE-6415** — Error "malformed string" is raised instead of "expected: N, actual: M" when UTF-8 charset is used and default value is longer than the column length.

fixed by A. dos Santos Fernandes
(CORE-6414) — Error "expected length N, actual M" contains wrong value of M when UTF-8 charset is used in the field declaration.

fixed by A. dos Santos Fernandes

(CORE-6408) — RETURNING clause in the MERGE statement cannot reference column in aliased target table using qualified reference (alias.column) if DELETE action present. Same fix was backported to Firebird 3.0.8.

fixed by A. dos Santos Fernandes

(CORE-6403) — Some PSQL statements may lead to exceptions report wrong line/column.

fixed by A. dos Santos Fernandes

(CORE-6398) — Error converting string with hex representation of INTEGER to SMALLINT.

fixed by A. Peshkov

(CORE-6397) — Message length error with COALESCE and TIME / TIMESTAMPS WITHOUT TIME ZONE and WITH TIME ZONE.

fixed by A. dos Santos Fernandes

(CORE-6389) — Using binary string literal to assign to user-defined blob sub-types yield conversion error.

fixed by A. dos Santos Fernandes

(CORE-6386) — ALTER SEQUENCE RESTART WITH <n> should not change the initial sequence START value.

fixed by A. dos Santos Fernandes

(CORE-6385) — Wrong line and column information after IF statement.

fixed by A. dos Santos Fernandes

(CORE-6379) — Bugcheck 179 (decompression overran buffer).
(CORE-6376) — IDENTITY column with explicit START WITH or INCREMENT BY starts with wrong value.

fixed by A. dos Santos Fernandes

(Core-6357) — LEAD() and LAG() do not allow to specify 3rd argument of INT128 datatype.

fixed by A. Peshkov

(Core-6356) — ROUND() does not allow second argument >=1 when its first argument is more than MAX_BIGINT / 10.

fixed by A. Peshkov

(Core-6355) — TRUNC() does not accept second argument = -128 (but shows it as required boundary in error message).

fixed by A. Peshkov

(Core-6353) — INT128 data type has problems with some PSQL objects.

fixed by A. Peshkov

(Core-6344) — Invalid return type for functions with INT128 / NUMERIC(38) argument.

fixed by A. Peshkov

(Core-6337) — Sub-type information is lost when calculating arithmetic expressions.

fixed by A. Peshkov

(Core-6336) — Error "Implementation of text subtype <NNNN> not located" on attempt to use some collations defined in fbintl.conf.

fixed by A. dos Santos Fernandes

(Core-6335) — INSERT ... RETURNING does not require a SELECT privilege.
fixed by D. Yemanov

(CORE-6328) — FB4 Beta 2 may still be using the current date for TIME WITH TIME ZONE and extended wire protocol.

fixed by A. dos Santos Fernandes

(CORE-6325) — NTILE/RANK/PERCENT_RANK may cause problems in big/complex statements.

fixed by A. dos Santos Fernandes

(CORE-6318) — CAST('NOW' as TIME) raises a conversion error.

fixed by A. dos Santos Fernandes

(CORE-6316) — Unable to specify new 32KB page size in CREATE DATABASE statement.

fixed by A. Peshkov

(CORE-6303) — Error writing to TIMESTAMP / TIME WITH TIME ZONE array.

fixed by A. Peshkov

(CORE-6302) — Error writing an array of NUMERIC(24,6) to the database.

fixed by A. Peshkov

(CORE-6084) — CREATE SEQUENCE START WITH has wrong initial value.

fixed by A. dos Santos Fernandes

(CORE-6023) — FB4 is unable to overwrite older ODS database.

fixed by A. Peshkov

(CORE-5838) — Rotated trace files are locked by the engine.

fixed by V. Khorsun
Chapter 14. Bugs Fixed

(CORE-4985) — A non-privileged user could implicitly count records in a restricted table.

fixed by D. Yemanov

(CORE-2274) — MERGE has a non-standard behaviour, accepts multiple matches.

fixed by V. Khorsun

Server Crashes/Hang-ups

(CORE-6450) — Races in the security databases cache could lead to the server crash. Same fix was backported to Firebird 3.0.8.

fixed by A. Peshkov

(CORE-6433) — Server could crash during a daily maintenance / set statistics index. Same fix was backported to Firebird 3.0.8.

fixed by A. Peshkov

(CORE-6412) — Firebird was freezing when trying to manage users via triggers. Same fix was backported to Firebird 3.0.8.

fixed by A. Peshkov

(CORE-6387) — Client process was aborting due to bugs inside the ChaCha plugin.

fixed by A. Peshkov

API/Remote Interface

(CORE-6432) — Possible buffer overflow in client library in Attachment::getInfo() call. Same fix was backported to Firebird 3.0.8.

fixed by A. Peshkov

(CORE-6426) — Assertion when the batch is executed without a BLOB field.

fixed by A. Peshkov
Exception in client library in IAttachment::createBatch().

fixed by A. Peshkov

Build Issues

Android port build failure.

fixed by A. Peshkov

Utilities

isql

Bad headers when text columns has >= 80 characters.

fixed by A. dos Santos Fernandes

gbak

Unable to restore database with tables using GENERATED ALWAYS AS IDENTITY columns.

fixed by A. Peshkov

Firebird 4.0 Beta 2 Release: Bug Fixes

The following bug-fixes since the Beta 1 release are noted:

Core Engine

Hex number used at the end of statement could read invalid memory and produce wrong values or exceptions. Same fix was backported to Firebird 3.0.6.

fixed by A. dos Santos Fernandes

Data type of MON$ATTACHMENTS.MON$IDLE_TIMER and MON$STATEMENTS.MON$STATEMENT_TIMER was defined as TIMESTAMP WITHOUT TIME ZONE, now it’s changed to TIMESTAMP WITH TIME ZONE.

fixed by A. dos Santos Fernandes
(CORE-6281) — Invalid timestamp errors could happen when working with the RDB$TIME_ZONE_UTIL.TRANSITIONS procedure.

fixed by A. dos Santos Fernandes

(CORE-6280) — MERGE statement could lose parameters in the “WHEN [NOT] MATCHED” clause that will never be matched. This could also cause server crashes in some situations. Same fix was backported to Firebird 3.0.6.

fixed by A. dos Santos Fernandes

(CORE-6272) — Failed attach to a database was not traced.

fixed by A. Peshkov

(CORE-6266) — Deleting records from MON$ATTACHMENTS using the ORDER BY clause didn’t close the corresponding attachments. Same fix was backported to Firebird 3.0.6.

fixed by D. Yemanov

(CORE-6251) — UNIQUE CONSTRAINT violation could be possible. Same fix was backported to Firebird 3.0.6.

fixed by V. Khorsun

(CORE-6250) — Signature mismatch error could be raised when creating package body on identical packaged procedure header. Same fix was backported to Firebird 3.0.6.

fixed by A. dos Santos Fernandes

(CORE-6248) — A number of errors could happen when database name is longer than 255 characters.

fixed by A. Peshkov

fixed by A. dos Santos Fernandes
Values greater than number of days between 01.01.0001 and 31.12.9999 (=3652058) could be added or subtracted from \texttt{DATE}.

\textit{fixed by A. dos Santos Fernandes}

\texttt{DECFLOAT}: subtraction (“\texttt{Num1 - Num2}”) would lead to the “Decimal float overflow” error if \texttt{Num2} is specified in scientific notation and is less than max double (1.7976931348623157e308).

\textit{fixed by A. Peshkov}

\texttt{RDB$TIME\_ZONE\_UTIL} package had wrong privilege defined for \texttt{PUBLIC}.

\textit{fixed by A. dos Santos Fernandes, D. Yemanov}

It was impossible to connect to a database if \texttt{security.db} reference was removed from \texttt{databases.conf}. Same fix was backported to Firebird 3.0.6.

\textit{fixed by A. Peshkov}

Incorrect implementation of \texttt{allocFunc()} for zlib1: memory leak was possible. Same fix was backported to Firebird 3.0.6.

\textit{fixed by A. Peshkov}

\texttt{tzdata} database version was outdated and required an update.

\textit{fixed by A. dos Santos Fernandes}

\texttt{VARCHARS} of insufficient length was used for command \texttt{SET BIND OF DECFLOAT TO VARCHARS}.

\textit{fixed by V. Khorsun}

Improper error was raised for \texttt{UNION DISTINCT} with more than 255 columns.

\textit{fixed by A. dos Santos Fernandes}

Original contents of the column used with \texttt{ENCRYPT()} looked as distorted after this
call.

fixed by A. Peshkov

(CORE-6181) — Usage of “SET DECFLOAT BIND BIGINT,n” with result of 11+ digits, would fail with the “Decimal float invalid operation” error.

fixed by A. Peshkov

(CORE-6166) — Some problems could appear for long object names (> 255 bytes).

fixed by A. dos Santos Fernandes

(CORE-6160) — SUBSTRING of non-text/-blob was described to return NONE character set in DSQL.

fixed by A. dos Santos Fernandes

(CORE-6159) — SUBSTRING SIMILAR was described with wrong data type in DSQL.

fixed by A. dos Santos Fernandes

(CORE-6110) — 64-bit transaction IDs were not stored properly inside the status vector.

fixed by I. Eremin

(CORE-6080) — Attempt to drop an existing user could randomly fail with error “336723990 : record not found for user”.

fixed by V. Khorsun

(CORE-6046) — Incorrect time zone parsing could read garbage in memory.

fixed by A. dos Santos Fernandes

(CORE-6034) — The original time zone was not set to the current time zone at the routine invocation.

fixed by A. dos Santos Fernandes
(CORE-6033) — SUBSTRING(CURRENT_TIMESTAMP ...) would fail with a “string truncation” error.

fixed by A. dos Santos Fernandes

(CORE-5957) — Adding a numeric quantifier as a bound for repetition of expression inside SIMILAR TO could lead to an empty resultset.

fixed by A. dos Santos Fernandes

(CORE-5931) — SIMILAR TO did not return the result when an invalid pattern was used.

fixed by A. dos Santos Fernandes

(CORE-5892) — SQL SECURITY DEFINER context was not properly evaluated for monitoring tables.

fixed by R. Simakov

(CORE-5697) — Conversion from numeric literals to DECIMAL would add the precision that is not originally present.

fixed by A. Peshkov

(CORE-5696) — Conversion from zero numeric literals to DECIMAL would lead to the incorrect result.

fixed by A. Peshkov

(CORE-5664) — SIMILAR TO was substantially (500-700x) slower than LIKE on trivial pattern matches with VARCHAR data.

fixed by A. dos Santos Fernandes

(CORE-4874) — Server could perform a SIMILAR TO matching infinitely.

fixed by A. dos Santos Fernandes

(CORE-4739) — Accent insensitive comparison: diacritical letters with diagonal crossing stroke failed for non-equality conditions with their non-accented forms.

fixed by A. dos Santos Fernandes
(CORE-3858) — Very poor performance of SIMILAR TO for some arguments.

fixed by A. dos Santos Fernandes

(CORE-3380) — It was possible to read from the newly created BLOB. It's prohibited now.

fixed by A. dos Santos Fernandes

### Server Crashes/Hang-ups

(CORE-6254) — Server could crash when using SET TRANSACTION and ON TRANSACTION START trigger uses EXECUTE STATEMENT against current transaction. Same fix was backported to Firebird 3.0.6.

fixed by V. Khorsun

(CORE-6253) — Locked fb_lock file could cause a server crash. Same fix was backported to Firebird 3.0.6.

fixed by V. Khorsun

(CORE-6251) — Server would crash when built-in function LEFT or RIGHT is missing its 2nd argument. Same fix was backported to Firebird 3.0.6.

fixed by A. dos Santos Fernandes

(CORE-6231) — Server would crash during shutdown of XNET connection to a local database when events have been registered. Same fix was backported to Firebird 3.0.6.

fixed by V. Khorsun

(CORE-6224) — Server could crash due to double destruction of the rem_port object. Same fix was backported to Firebird 3.0.6.

fixed by D. Kovalenko, A. Peshkov

(CORE-6218) — COUNT(DISTINCT DECFLOAT_FIELD) could cause the server to crash when there are duplicate values in this field.

fixed by A. Peshkov
Chapter 14. Bugs Fixed

(CORE-6217) — Dangerous (possibly leading to a crash) work with pointer: `delete ptr; ptr=new ;`

fixed by D. Kovalenko, A. Peshkov

(CORE-5972) — External engine trigger would crash the server if the table has computed fields. Same fix was backported to Firebird 3.0.6.

fixed by A. dos Santos Fernandes

(CORE-4893) — Similar to would cause a server crash when matching a blob with size >2GB to a string literal.

fixed by A. dos Santos Fernandes

**API/Remote Interface**

(CORE-6283) — Result of `isNull()` in message metadata, returned by metadata builder, did not match datatype set by `setType()` in metadata builder. Same fix was backported to Firebird 3.0.6.

fixed by A. Peshkov

(CORE-6227) — `isc_info_svc_user_dbpath` was always returning an alias of the main security database. Same fix was backported to Firebird 3.0.6.

fixed by A. Peshkov

(CORE-6212) — Authentication plugin on the server could read garbage data from the client instead of the empty packet.

fixed by A. Peshkov

(CORE-6207) — It was impossible to compile Firebird.pas with FPC.

fixed by A. Peshkov

**Build Issues**

(CORE-6174) — `ibase.h` was missing from the nightly builds.

fixed by A. dos Santos Fernandes
(CORE-6170) — Installation on CentOS 8 failed because of the mismatched version of LibTomMath and LibNCurses libraries.

*fixed by A. Peshkov*

(CORE-6061) — It was impossible to build the server with the `--with-builtintommath` option.

*fixed by A. Peshkov*

(CORE-6056) — Overflow warnings appeared when building some collations.

*fixed by A. dos Santos Fernandes*

(CORE-6019) — Wire compression did not work without the MSVC 2010 runtime package installed.

*fixed by V. Khorsun*

(CORE-5691) — File description of the Firebird executables was not specific.

*fixed by V. Khorsun*

(CORE-5445) — Installation failed on Debian Stretch/Testing due to incorrect version of the LibTomMath library.

*fixed by A. Peshkov*

**Utilities**

**isql**

(CORE-6262) — `SHOW DOMAIN/TABLE` did not display the character set of system objects.

*fixed by A. dos Santos Fernandes*

(CORE-6260) — Warnings were not always displayed in ISQL. Same fix was backported to Firebird 3.0.6.

*fixed by A. Peshkov*
— Command “isql -x” could not extract the ROLE name when using a multi-byte charset for the connection.

fixed by A. dos Santos Fernandes

— Metadata script extracted with ISQL from a database restored from a v2.5 backup was invalid if some table has COMPUTED BY fields. Same fix was backported to Firebird 3.0.6.

fixed by A. dos Santos Fernandes

— Some issues were noticed due to the increased SQL identifier length.

fixed by A. dos Santos Fernandes

### gbak

— Existing mapping rules were removed by the backup/restore cycle. Same fix was backported to Firebird 3.0.6.

fixed by A. Peshkov

— Wrong dependencies of stored function on view were created after backup/restore. Same fix was backported to Firebird 3.0.6.

fixed by A. dos Santos Fernandes

— CREATE DATABASE permission would disappear from security database after the backup/restore cycle. Same fix was backported to Firebird 3.0.6.

fixed by A. Peshkov

— Creating backup to STDOUT using the service manager was broken. Same fix was backported to Firebird 3.0.6.

fixed by A. Peshkov

— Restoring an encrypted backup of a SQL dialect 1 database would fail.

fixed by A. Peshkov
(CORE-5976) — GBAK multi-database file restore used wrong minimum number of pages for the first database file.

fixed by M. Rotteveel

(CORE-2251) — GBAK doesn’t return the error code in some cases. Same fix was backported to Firebird 3.0.6.

fixed by A. Peshkov

gfix

(CORE-5364) — gfix -online normal did not raise an error when there was another SYSDBA-owned session open. Same fix was backported to Firebird 3.0.6.

fixed by A. Peshkov

Firebird 4.0 Beta 1 Release: Bug Fixes

The following bug-fixes since the Alpha release are noted:

Core Engine

(CORE-5986) — Evaluation of NULL IS [NOT] FALSE | TRUE was incorrect. Same fix was backported to Firebird 3.0.5.

fixed by A. dos Santos Fernandes

(CORE-5985) — Regression: ROLE was not being passed to ES/EDS: specifying it in the statement was ignored. Same fix was backported to Firebird 3.0.5.

fixed by A. Peshkov

(CORE-5982) — An error involving read permission for a BLOB field was being thrown when the BLOB was an input or output parameter for a procedure. Same fix was backported to Firebird 3.0.5.

fixed by D. Starodubov

(CORE-5974) — SELECT DISTINCT with a decfloat/timezone/collated column was producing wrong results.
(CORE-5973) — Improvement: Fixed-point overflow in a DOUBLE PRECISION value converted from DECFLOAT is now handled properly.

fixed by A. Peshkov

(CORE-5965) — The optimizer was choosing a less efficient plan in FB4 and FB3 than the FB2.5 optimizer. Same fix was backported to Firebird 3.0.5.

fixed by D. Yemanov

(CORE-5959) — Firebird would return the wrong time after a change of time zone. Same fix was backported to Firebird 3.0.5.

fixed by V. Khorsun

(CORE-5950) — Deadlock could occur when attaching to a bugchecked database. Same fix was backported to Firebird 3.0.5.

fixed by A. Peshkov

(CORE-5949) — Bugcheck could happen when a read-only database with non-zero linger was set to read-write mode. Same fix was backported to Firebird 3.0.5.

fixed by V. Khorsun

(CORE-5935) — Bugcheck 165 (cannot find TIP page). Same fix was backported to Firebird 3.0.5.

fixed by V. Khorsun

(CORE-5930) — Bugcheck with message “incorrect snapshot deallocation - too few slots”.

fixed by V. Khorsun

(CORE-5918) — Memory pool statistics were inaccurate. Same fix was backported to Firebird 3.0.5.

fixed by A. Peshkov
(CORE-5896) — A NOT NULL constraint was not being synchronized after the column was renamed.

fixed by A. dos Santos Fernandes

(Core-5785) — An ORDER BY clause on a compound index could disable usage of other indices. Same fix was backported to Firebird 3.0.5.

fixed by D. Yemanov

(Core-5871) — Incorrect caching of the result of a subquery result in a procedure call from a SELECT query.

fixed by A. dos Santos Fernandes

(Core-5862) — RDB$CHARACTER_LENGTH in RDB$FIELDS was not being populated when the column was a computed VARCHAR without an explicit type.

fixed by A. dos Santos Fernandes

(Core-5750) — Date-time parsing needed strengthening.

fixed by A. dos Santos Fernandes

(Core-5728) — The field subtype of DEC_FIXED columns was not returned by isc_info_sql_sub_type.

fixed by A. Peshkov

(Core-5726) — The error message when inserting a value exceeding the maximum value of DEC_FIXED decimal was unclear.

fixed by A. Peshkov

(Core-5717) — The literal date/time prefix syntax (DATE, TIME or TIMESTAMP prefix before the quoted value) used together with the implicit date/time literal expressions ('NOW', 'TODAY', etc.) was known to evaluate those expressions in ways that would produce unexpected results, often undetected. This behaviour was considered undesirable — the Firebird 4.0 engine and above will now reject them everywhere.

For details, see Prefixed Implicit Date/Time Literals Now Rejected in the Compatibility chapter.
Chapter 14. Bugs Fixed

*(CORE-5710)* — Data type declaration DECFLOAT without precision should be using a default precision.

*fixed by A. Peshkov*

*(CORE-5700)* — DECFLOAT underflow should yield zero instead of an error.

*fixed by A. Peshkov*

*(CORE-5699)* — DECFLOAT should not throw exceptions when +/-NaN, +/-sNaN and +/-Infinity is used in comparisons.

*fixed by A. Peshkov*

*(CORE-5646)* — A parse error when compiling a statement would cause a memory leak until the attachment was disconnected.

*fixed by A. dos Santos Fernandes*

*(CORE-5612)* — View operations (create, recreate or drop) were exhibiting gradual slow-down.

*fixed by D. Yemanov*

*(CORE-5611)* — Memory consumption for prepared statements was higher.

*fixed by A. dos Santos Fernandes*

*(CORE-5593, CORE-5518)* — The system function RDB$ROLE_IN_USE could not take long role names.

*fixed by A. Peshkov*

*(CORE-5480)* — A SUBSTRING start position smaller than 1 should be allowed.

*fixed by A. dos Santos Fernandes*

*(CORE-1592)* — Altering procedure parameters could lead to an unrestorable database.
Server Crashes/Hang-ups

(CORE-5980) — Firebird would crash due to concurrent operations with expression indices. Same fix was backported to Firebird 3.0.5.

fixed by V. Khorsun

(CORE-5972) — External engine trigger could crash the server if the table had a computed field.

fixed by A. dos Santos Fernandes

(CORE-5943) — The server could crash while preparing a query with both DISTINCT/ORDER BY and a non-field expression in the select list. Same fix was backported to Firebird 3.0.5.

fixed by D. Yemanov

(CORE-5936) — The server could segfault at the end of a database backup.

fixed by V. Khorsun

Security

(CORE-5927) — With some non-standard authentication plugins, traffic would remain unencrypted despite providing the correct crypt key. Same fix was backported to Firebird 3.0.5.

fixed by A. Peshkov

(CORE-5926) — An attempt to create a mapping with a non-ASCII user name that was encoded in a single-byte codepage (e.g. WIN1251) would lead to a “Malformed string” error. Same fix was backported to Firebird 3.0.5.

fixed by A. Peshkov

(CORE-5861) — New objects and some old objects in a database could not be granted the GRANT OPTION via role privileges.

fixed by R. Simakov
(CORE-5657) — Attended to various UDF-related security vulnerabilities, resulting in aggressive deprecation of support for the use of UDFs as external functions. See also External Functions (UDFs) Feature Deprecated in the the chapter Changes to the Firebird Engine and Deprecation of External Functions (UDFs) in the Compatibility chapter.

fixed by A. Peshkov

(CORE-5639) — Mapping rule using WIN_SSPI plugin: Windows user group conversion to Firebird role was not working.

fixed by A. Peshkov

(CORE-5518) — Firebird UDF string2blob() could allow remote code execution.

fixed by A. Peshkov

Utilities

gbak

(CORE-5855) — A database with generators containing space characters in their names could not be backed up.

fixed by A. Peshkov

(CORE-5800) — After backup/restore, expression indexes on computed fields would not work properly. Same fix was backported to Firebird 3.0.5.

fixed by D. Yemanov

(CORE-5637) — A string right truncation error was occurring on restore of the security database.

fixed by A. Peshkov

gpre

(CORE-5834) — gpre_boot was failing to link using cmake, giving undefined reference ‘dladdr’ and ‘dlerror’. Same fix was backported to Firebird 3.0.5.

fixed by A. Peshkov
**trace**

*(CORE-5907)* — Regression: Trace could not be launched if its ‘database’ section contained a regular expression pattern with curvy brackets to enclose a quantifier. Same fix was backported to Firebird 3.0.5.

*fixed by A. Peshkov*

---

**Build Issues**

*(CORE-5989)* — Some build issues involving iconv / libiconv 1.15 vs libc / libiconv_open | common/isc_file.cpp. Same fix was backported to Firebird 3.0.5.

*fixed by A. Peshkov*

---

*(CORE-5955)* — Static linking problem with ld >= 2.31. Same fix was backported to Firebird 3.0.5.

*fixed by R. Simakov*

---

**Firebird 4.0 Alpha 1 Release: Bug Fixes**

The following fixes to pre-existent bugs are noted:

*(CORE-5545)* — Using the POSITION parameter with the [RE]CREATE TRIGGER syntax would cause an “unknown token” error if POSITION was written in the logically correct place, i.e. after the main clauses of the statement. For example, the following should work because POSITION comes after the other specifications:

```
RECREATE TRIGGER T1
BEFORE INSERT
ON tbl
POSITION 1 AS
BEGIN
  --
END
```

However, it would exhibit the error, while the following would succeed:
RECREATE TRIGGER T1
BEFORE INSERT
POSITION 1
ON tbl
AS
BEGIN
    --
END

The fix makes the first example correct, and the second should throw the error.

fixed by A. dos Santos Fernandes

(CORE-5454) — Inserting into an updatable view without an explicit column list would fail.

fixed by A. dos Santos Fernandes

(CORE-5408) — The result of a Boolean expression could not be concatenated with a string literal.

fixed by A. dos Santos Fernandes

(CORE-5404) — Inconsistent column and line references were being returned in error messages for faulty PSQL definitions.

fixed by A. dos Santos Fernandes

(CORE-5237) — Processing of the include clause in configuration files was mishandling dot (‘.’) and asterisk (‘*’) characters in the file name and path of the included file.

fixed by D. Sibiryakov

(CORE-5223) — Double dots in file names for databases were prohibited if the DatabaseAccess configuration parameter was set to restrict access to a list of directories.

fixed by D. Sibiryakov

(CORE-5141) — Field definition would allow multiple NOT NULL clauses. For example,

create table t (a integer not null not null not null not null)
The fix makes the behaviour consistent with `CREATE DOMAIN` behaviour, and the example will return the error “Duplicate specification of NOT NULL - not supported”.

fixed by D. Sibiryakov

(CORE-4701) — Garbage collection for indexes and BLOBs was not taking data in the Undo log into account.

fixed by D. Sibiryakov

(CORE-4483) — In PSQL, data changed by executing a procedure was not visible to the `WHEN` handler if the exception occurred in the called procedure.

fixed by D. Sibiryakov

(CORE-4424) — In PSQL, execution flow would roll back to the wrong savepoint if multiple exception handlers were executed at the same level.

fixed by D. Sibiryakov
# Chapter 15. Firebird 4.0 Project Teams

## Table 4. Firebird Development Teams

<table>
<thead>
<tr>
<th>Developer</th>
<th>Country</th>
<th>Major Tasks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dmitry Yemanov</td>
<td>Russian Federation</td>
<td>Full-time database engineer/implementor; core team leader</td>
</tr>
<tr>
<td>Alex Peshkov</td>
<td>Russian Federation</td>
<td>Full-time security features coordinator; buildmaster; porting authority</td>
</tr>
<tr>
<td>Vladyslav Khorsun</td>
<td>Ukraine</td>
<td>Full-time DB engineer; SQL feature designer/implementor</td>
</tr>
<tr>
<td>Adriano dos Santos Fernandes</td>
